Guidelines on the cryptographic algorithms, accompanying the usage of standards GOST R 34.10-2012 and GOST R 34.11-2012
draft-smyshlyaev-gost-usage-07

Abstract

The purpose of this document is to make the specifications of the cryptographic algorithms defined by GOST R 34.10-2012 and GOST R 34.11-2012 standards available to the Internet community for their implementation in the cryptographic protocols based on the accompanying algorithms.

These specifications define the pseudorandom functions, the key agreement algorithm based on Diffie-Hellman algorithm, the parameters of elliptic curves, the key derivation functions and the key export functions.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on February 7, 2016.
1. Introduction

The accompanying algorithms are intended for the cryptographic protocols implementation. This memo contains a description of the accompanying algorithms based on Russian national standards GOST R 34.10-2012 [GOST3410-2012] and GOST R 34.11-2012 [GOST3411-2012].
English versions of these standards can be found in [RFC7091] and [RFC6986].

The specifications of algorithms and parameters proposed in this memo are provided on the basis of experience in the development of the cryptographic protocols, as described in the [RFC4357], [RFC4490] and [RFC4491].

This memo contains a description of the accompanying algorithms defining the pseudorandom functions, the key agreement algorithm based on Diffie-Hellman algorithm, the parameters of elliptic curves, the key derivation functions and the key export functions.

The main reason for the development of this document is the need to ensure compatibility of the cryptographic protocol implementation based on the Russian cryptographic standards GOST R 34.10-2012 [GOST3410-2012] and GOST R 34.11-2012 [GOST3411-2012].

2. Scope

This memo is recommended for usage in encryption and protection the authenticity of the data based on the usage of the digital signature algorithms GOST R 34.10-2012 [GOST3410-2012] and hash function GOST R 34.11-2012 [GOST3411-2012] in public and corporate networks to protect information that does not contain a classified information.

3. Conventions used in This Document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

3.1. Notation

This document uses the following notation for the sets and operations on the elements of these sets in accordance with GOST R 34.11-2012 [GOST3411-2012]:

- (xor) exclusive-or of two binary vectors of the same length;
- $V_n$ the finite-dimensional vector space over GF(2) of dimension n with the (xor) operation, for $n = 0$ the $V_0$ space consists of a single empty element of size 0;
- $U$ the element of $V_n$; in the binary representation $U = (u_{(n-1)}, u_{(n-2)}, \ldots, u_1, u_0)$, where $u_i$ in {0, 1};
A|B concatenation of vectors A, B, i.e., if A in V_n1, B in V_n2, A = (a_(n1-1), a_(n1-2), ... , a_0), and B = (b_(n2-1), b_(n2-2), ... , b_0), then A|B = (a_(n1-1), a_(n1-2), ... , a_0, b_(n2-1), b_(n2-2), ... , b_0) is an element of V_(n1+n2);

V_8(r) the set of byte strings of size r; if W is an element of V_8(r), then W = (w^0, w^1, ..., w^(r-1)), where w^0, w^1, ..., w^(r-1) are elements of V_8; if A in V_8(r1), B in V_8(r2), A = (a^0, a^1, ..., a^(r1-1)), and B = (b^0, b^1, ..., b^(r2-1)), then A|B = (a^0, a^1, ..., a^(r1-1), b^0, b^1, ..., b^(r2-1)) is an element of V_8(r1+r2);

Bit representation the bit representation of the element W = (w^0, w^1, ..., w^(r-1)) of V_8(r), where w^0 = (w_7, w_6, ..., w_0), w^1 = (w_15, w_14, ..., w_8), ..., w^(r-1) = (w_(8r-1), w_(8r-2), ..., w_(8r-8)) are elements of V_8, is an element (w_(8r-1), w_(8r-2), ..., w_1, w_0) of V_(8*r);

Byte representation if n is a multiple of 8, r = n/8, then the byte representation of the element W = (w_(n-1), w_(n-2), ..., w_0) of V_n is a byte string (w^0, w^1, ..., w^(r-1)) of V_8(r), where w^0 = (w_7, w_6, ..., w_0), w^1 = (w_15, w_14, ..., w_0), ..., w^(r-1) = (w_(8r-1), w_(8r-2), ..., w_(8r-8)) are elements of V_8;

K (key) arbitrary element of V_n; if K in V_n, then its size (in bits) is equal to n, where n can be an arbitrary natural number.

Note: It is proposed to interpret and edit the formulas in accordance with the above definitions.

3.2. Basic terms and definitions

This memo uses the following terms, abbreviations and symbols:
<table>
<thead>
<tr>
<th>Symbols</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>H_256</td>
<td>GOST R 34.11-2012 hash function, 256-bit</td>
</tr>
<tr>

<td>GOST R 34.11-2012 hash function, 512-bit</td>
</tr>
<tr>
<td>HMAC</td>
<td>a function for calculating a message authentication code, based on hash function in accordance with [RFC2104]</td>
</tr>
<tr>
<td>HMAC_256</td>
<td>an HMAC function based on the hash function H_256, intended for computing a message authentication code</td>
</tr>
<tr>
<td>HMAC_512</td>
<td>an HMAC function based on the hash function H_512, intended for computing a message authentication code</td>
</tr>
<tr>
<td>PRF</td>
<td>a pseudorandom function, i.e., a transformation that allows to generate pseudorandom sequence of bytes</td>
</tr>
<tr>
<td>KDF</td>
<td>a key derivation function, i.e., a transformation, that allows to derive keys and keying material for the root key and random data using a pseudorandom function</td>
</tr>
</tbody>
</table>

To produce a byte sequence of the size $r$ with functions that give a longer output the input should be taken from the output sequence of the first $r$ bytes. This remark applies to the following functions:

- the functions described in Section 4.2;
- KDF_TREE_GOSTR3411_2012_256.

When $n$ is multiple of 8, an element of $V_n$ can be represented both in the bit and byte form. The result of operation $<<|>>$, applied to the elements in the bit representation is described in the bit representation. The result of the operation $<<|>>$, applied to the same elements in byte representation has the byte representation. Thus, the symbol $<<|>>$ is used to refer to two different operations, depending on the form of their arguments. The operation is uniquely determined by the representation of arguments.

Hereinafter all data (the elements of $V_n$) are considered given in the byte representation unless otherwise specified. Operation $<<|>>$ on the arguments of functions, unless explicitly stated, is performed on their byte representation.
If the function is defined outside this document (eg, $H_{256}$) and its definition requires arguments in bit representation, it is assumed that the bit representation of the argument is formed immediately before the calculation of the function (in particular, immediately after the application of the operation $\ll|\gg$ to the byte representation of the arguments).

If the output of another function that is defined outside of this document is used as the argument of the function defined below and has output value in bit representation, it is assumed that the output value will be translated into the byte representation before substitution in arguments.

4. Algorithm descriptions

For the algorithms described in this paper the possible values of the functions are limited by the permissibility of applying them as the input parameter of the transformations and are assigned by the protocols.

4.1. HMAC functions

This section defines the HMAC transformations based on GOST R 34.11-2012 [GOST3411-2012] algorithms.

4.1.1. HMAC_GOSTR3411_2012_256

This HMAC transformation is based on GOST R 34.11-2012 [GOST3411-2012] algorithm, 256-bit output. The identifier of this transformation is shown below:

$\text{id-tc26-hmac-gost-3411-12-256}, \langle\langle\text{iso}(1)\ member-body(2)\ ru(643)\ rosstandart(7)\ tc26(1)\ algorithms(1)\ mac(4)\ hmac-gost-3411-12-256(1)\rangle\rangle$.

This algorithm uses $H_{256}$ as a hash function for HMAC, described in [RFC2104]. The method of forming the values of ipad and opad is also specified in [RFC2104]. The size of the HMAC_256 output in bytes is equal to 32, the block size of the iterative procedure for the $H_{256}$ compression function in bytes is equal to 64 (in the notation of [RFC2104], $L = 32$ and $B = 64$, respectively).

4.1.2. HMAC_GOSTR3411_2012_512

This HMAC transformation is based on GOST R 34.11-2012 [GOST3411-2012] algorithm, 512-bit output. The identifier of this transformation is shown below:
This algorithm uses $H_{512}$ as a hash function for HMAC, described in [RFC2104]. The method of forming the values of $ipad$ and $opad$ is also specified in [RFC2104]. The size of the HMAC_512 output in bytes is equal to 64, the block size of the iterative procedure for the $H_{512}$ compression function in bytes is equal to 64 (in the notation of [RFC2104], $L = 64$ and $B = 64$, respectively).

### 4.2. PRF

This section defines six HMAC-based PRF transformations recommended for usage. Two of them are designed for the TLS protocol and four are designed for the IPsec protocol.

#### 4.2.1. PRFs for the TLS protocol

##### 4.2.1.1. PRF_TLS_GOSTR3411_2012_256

This is the transformation providing the pseudorandom function of the TLS protocol in accordance with GOST R 34.11-2012 [GOST3411-2012]; the transformation uses $P_{GOSTR3411_2012_256}$ function that is similar to the $P_{hash}$ function in Section 5 of [RFC2246], where HMAC_256 function (defined in Section 4.1.1) is used as an HMAC_hash function.

\[
PRF_{TLS\_GOSTR3411\_2012\_256} (secret, label, seed) = \ P_{GOSTR3411_2012_256} (secret, label \parallel seed).
\]

##### 4.2.1.2. PRF_TLS_GOSTR3411_2012_512

This is the transformation providing the pseudorandom function of the TLS protocol in accordance with GOST R 34.11-2012 [GOST3411-2012]; the transformation uses $P_{GOSTR3411_2012_512}$ function that is similar to the $P_{hash}$ function in Section 5 of [RFC2246], where HMAC_512 function (defined in Section 4.1.2) is used as an HMAC_hash function.

\[
PRF_{TLS\_GOSTR3411\_2012\_512} (secret, label, seed) = \ P_{GOSTR3411_2012_512} (secret, label \parallel seed).
\]

#### 4.2.2. PRFs for the IPsec protocols based on GOST R 34.11-2012

IPsec family protocols make use of pseudorandom functions for the purposes of keying material generation and authentication. Specifications for the version 1 (IKEv1) [RFC2409] and version 2 (IKEv2) [RFC7296] of the Internet Key Exchange protocol contain definitions of using PRF in various parts of the protocols.
4.2.2.1. PRF in the IKEv1 protocol

According to the Section 4 of [RFC2409] if a PRF is not negotiated, the HMAC based on the negotiated hash algorithm is used. So, when GOST R 34.11-2012 [GOST3411-2012] is used as a hash function in IKEv1, either HMAC_GOST3411_2012_256 or HMAC_GOST3411_2012_512 are used as a PRF depending on the negotiated hash algorithm.

4.2.2.2. PRF in the IKEv2 protocol

IKEv2 has no default PRF. This document specifies that for IKEv2 either HMAC_GOST3411_2012_256 or HMAC_GOST3411_2012_512 must be used as PRF.

4.3. VKO algorithms for key agreement

This section identifies the key agreement algorithms using GOST R 34.10-2012 [GOST3410-2012].

4.3.1. VKO_GOSTR3410_2012_256

The VKO_GOSTR3410_2012_256 transformation is used for an agreement of the VKO 256-bit keys and is based on GOST R 34.11-2012 [GOST3411-2012], 256-bit. This algorithm can be applied for a key agreement using the GOST R 34.10-2012 [GOST3410-2012] 256-bit and 512-bit keys.

The algorithm is designed to produce an encryption key or a keying material of size 256 bits to be used in various cryptographic protocols. Key or keying material KEK_VKO (x, y, UKM) is produced by the side of communication from his private key x, the public key y*P of the opposite side and UKM value, considered as a number.

The algorithm can be used for deriving both static and ephemeral key with the public key size n >= 512 bits including the case where one side uses a static key and the other - ephemeral.

UKM parameter is optional (the default UKM = 1) and can take any value from 1 to 2^(n/2)-1. It is allowed to use a nonzero UKM of arbitrary size not exceeding n/2 bits. If at least one of the parties uses static keys, the recommended length of UKM is 64 bit or more.

K is calculated using formula

\[ K (x, y, UKM) = (m/q*UKM*x \mod q)*(y*P), \]
where \( m \) and \( q \) are the parameters of the elliptic curve defined in the GOST R 34.10-2012 [GOST3410-2012] notation.

KEK_VKO is calculated using formula

\[
\text{KEK}_\text{VKO} \, (x, \, y, \, \text{UKM}) = H_{256} \, (K(x, \, y, \, \text{UKM})).
\]

This algorithm is defined similar to Section 5.2 of [RFC4357], but applies the hash function \( H_{256} \) instead of the hash function GOST R 34.11-94 [GOST3411-94] (referred as gostR3411) and \( K(x, \, y, \, \text{UKM}) \) is calculated with public key size \( n \geq 512 \) bits and UKM size up to \( n/2 \) bits.

### 4.3.2. VKO_GOSTR3410_2012_512

The VKO_GOSTR3410_2012_512 transformation is used for an agreement of the VKO 512-bit keys and is based on GOST R 34.11-2012 [GOST3411-2012], 512-bit. This algorithm can be applied for a key agreement using the GOST R 34.10-2012 [GOST3410-2012] 512-bit keys.

The algorithm is designed to produce an encryption key or keying material of size 512 bits to be used in cryptographic protocols. Key or keying material \( \text{KEK}_\text{VKO} \, (x, \, y, \, \text{UKM}) \) is produced by the exchange participant from his private key \( x \), the public key \( y*P \) of the opposite side and the UKM value, considered as a number.

The algorithm can be used for both static and ephemeral key with the public key size \( n \geq 1024 \) bits including the case where one side uses a static key and the other uses an ephemeral one.

UKM parameter is optional (the default UKM = 1) and can take any value from 1 to \( 2^{n/2} - 1 \). It is allowed to use a nonzero UKM of arbitrary size not exceeding \( n/2 \) bits. If at least one of the parties uses static keys, the recommended length of UKM is 128 bit or more.

\[
K \, (x, \, y, \, \text{UKM}) = (m/q*\text{UKM}*x \mod q)*(y*P),
\]

where \( m \) and \( q \) - the parameters of the elliptic curve according GOST R 34.10-2012 [GOST3410-2012] notation.

\[
\text{KEK}_\text{VKO} \, (x, \, y, \, \text{UKM}) = H_{512} \, (K \, (x, \, y, \, \text{UKM})).
\]

This algorithm is defined similar to Section 5.2 of [RFC4357], but instead of the hash function GOST R 34.11-94 [GOST3411-94] (referred as gostR3411) applies the hash function \( H_{256} \), and \( K(x, \, y, \, \text{UKM}) \) is calculated at the public key size \( n \geq 1024 \) bits and UKM size up to \( n/2 \) bits.
4.4. Key derivation function KDF_GOSTR3411_2012_256

The key derivation function KDF_GOSTR3411_2012_256 based on HMAC_256 function is designed to generate a 256-bit keying material and is given by:

\[
KDF (K_{in}, \text{label}, \text{seed}) = \text{HMAC}_256 (K_{in}, 0x01 \mid \text{label} \mid 0x00 \mid \text{seed} \mid 0x01 \mid 0x00),
\]

where

- \(K_{in}\) -- derivation key,
- \(\text{label}, \text{seed}\) -- the parameters, fixed and assigned by a protocol.

The key derivation function KDF_GOSTR3411_2012_256 is a special case of KDF_TREE_GOSTR3411_2012 function, described in the next section.

4.5. Key derivation function KDF_TREE_GOSTR3411_2012_256

The key derivation function KDF_TREE_GOSTR3411_2012_256 based on HMAC_256 and is given by:

\[
KDF_{\text{TREE}} (K_{in}, \text{label}, \text{seed}, R) = K(1) \mid K(2) \mid K(3) \mid K(4) \mid \ldots,
\]

\[
K(i) = \text{HMAC}_256 (K_{in}, [i]_2 \mid \text{label} \mid 0x00 \mid \text{seed} \mid [L]_2), i >= 1,
\]

where

- \(R\) a fixed external parameter, with possible values of 1, 2, 3 or 4;
- \(K_{in}\) derivation key;
- \(L\) the required size (in bits) of the generated keying material (an integer, not exceeding \(256 \times (2^{8 \times (8 \times R) - 1})\));
- \([L]_2\) byte representation of \(L\), in network byte order;
- \(i\) iteration counter;
- \([i]_2\) byte representation of the iteration counter (in the network byte order), the number of bytes in the representation \([i]_2\) is equal to \(R\) (no more than 4 bytes);
- \(\text{label}, \text{seed}\) the parameters, fixed and assigned by a protocol.
The key derivation function KDF_TREE_GOSTR3411_2012_256 is intended for generating a keying material in size of $L$, not exceeding $256 \times (2^{8 \times R} - 1)$ bits, and utilizes general principles of the input and output for the key derivation function outlined in Section 5.1 of NIST SP 800-108 [NISTSP800-108]. HMAC_256 algorithm with 256-bit output described in Section 4.1.1 is selected as a pseudorandom function.

When $R = 1$ and $L = 256$ the function KDF_TREE_GOSTR3411_2012_256 is equivalent to KDF_GOSTR3411_2012_256 from the previous section.

Each key derived from the keying material formed using the derivation key $K_{in}$ (0-level key) may be a 1-level diversification key and may be used to generate a new keying material. The keying material derived from the 1-level derivation key, can be split down into the 2nd level derivation keys. The application of this procedure leads to the construction of the key tree with the root key and the formation of the keying material to the hierarchy of the levels, as described in Section 6 of NIST SP 800-108 [NISTSP800-108]. The partitioning procedure for keying material at each level is defined according to the specific protocols.

4.6. Key wrap and unwrap

Wrapped representation of the secret key $K$ (GOST R 34.10-2012 [GOST3410-2012] key or GOST 28147-89 [GOST28147-89] key) is formed as follows by using a given export key $K_{e}$ (GOST 28147-89 [GOST28147-89] key) and a random UKM vector from 8 to 16 bytes in size:

1. Generate a random UKM vector.

2. With the key derivation function, using export key $K_{e}$ as a derivation key, and a UKM vector as the value of seed, generate a key, denoted by KEK$_{e}$ (UKM), where

   $$KEK_{e} (UKM) = KDF (K_{e}, \text{label}, \text{UKM}),$$

   where KDF function (see previous section) is used as a key derivation function for the fixed value

   $$\text{label} = (0x26 \mid 0xBD \mid 0xB8 \mid 0x78),$$

   and the seed value that is equal to UKM.

3. MAC value GOST 28147-89 (4-byte) for the data $K$ and the key KEK$_{e}$ (UKM) is calculated, initialization vector (IV) in this case is equal to the first 8 bytes of UKM. The resulting value is denoted as CEK_MAC.
4. The key $K$ is encrypted by the GOST 28147-89 algorithm in the Electronic Codebook (ECB) mode with the key $KEK_e (UKM)$. The encoding result is denoted as $CEK_{ENC}$.

5. The wrapped representation of the key is considered $(UKM \mid CEK_{ENC} \mid CEK_{MAC})$.

During the key import the value of key $K$ is restored as follows from the wrapped representation of the key (GOST R 34.10-2012 [GOST3410-2012] key or GOST 28147-89 key [GOST28147-89] key) and the export key $K_e$:

1. From the wrapped representation of the key selects the sets $UKM$, $CEK_{ENC}$, and $CEK_{MAC}$.

2. With the key derivation function, using the export key $K_e$ as a derivation key, and a random $UKM$ value as the value of seed, generates a key, denoted by $KEK_e(UKM)$, where

   $$ KEK_e (UKM) = KDF (K_e, label, UKM). $$

3. The $CEK_{ENC}$ set is decrypted by the GOST 28147-89 algorithm in the Electronic Codebook (ECB) mode with the key $KEK_e(UKM)$. The unwrapped key $K$ is assumed to be equal to the result of decryption.

4. MAC value GOST 28147-89 (4-byte) for the data $K$ and the key $KEK_e(UKM)$ is calculated, initialization vector (IV) in this case is equal to the first 8 bytes of $UKM$. If the result does not equal to $CEK_{MAC}$, an error is returned.

The algorithms for wrapping and unwrapping of the GOST R 34.10-2012 [GOST3410-2012] keys are modifications of the CryptoPro Key Wrap and CryptoPro Key Unwrap algorithms, described in Sections 6.3 and 6.4 of [RFC4357].

5. The parameters of elliptic curves

This section defines the elliptic curves parameters and identifiers that are recommended for the usage with signature and verification algorithms of digital signature in accordance with GOST R 34.10-2012 [GOST3410-2012] standard and with the key agreement algorithms VKO_GOSTR3410_2012_256 and VKO_GOSTR3410_2012_512.

This document does not negate the use of other parameters of the elliptic curves.
5.1. Canonical form

This section defines the elliptic curves parameters of the GOST R 34.10-2012 [GOST3410-2012] standard for the case of elliptic curves with a prime 512-bit modulus in canonical (Weierstrass) form, that is given by the following equation defined in GOST R 34.10-2012 [GOST3410-2012]:

\[ y^2 = x^3 + ax + b. \]

In case of an elliptic curves with 256-bit the parameters defined in [RFC4357] are proposed to use.

5.1.1. Parameters and identifiers

The parameters for each of the elliptic curve are represented by the following values which are defined in GOST R 34.10-2012 [GOST3410-2012]:

- \( p \) the elliptic curve modulus;
- \( a, b \) the coefficients of the equation of the elliptic curve in the canonical form;
- \( q \) the order of the elliptic curve;
- \( (x, y) \) the coordinates of a point \( P \) (generator of the prime order group) of the elliptic curve in the canonical form.

Both sets of the parameters are presented as ASN structures of the form:

```asn1
SEQUENCE {
    a    INTEGER,
    b    INTEGER,
    p    INTEGER,
    q    INTEGER,
    x    INTEGER,
    y    INTEGER
}
```

The parameter sets have the following identifiers:

1. id-tc26-gost-3410-12-512-paramSetA, <<iso(1) member-body(2)
   ru(643) rosstandart(7) tc26(1) constants(2) sign-constants(1)
gost-3410-12-512-constants(2) paramSetA(1)>>;
2.  id-tc26-gost-3410-12-512-paramSetB, <<iso(1) member-body(2)
    ru(643) rosstandart(7) tc26(1) constants(2) sign-constants(1)
    gost-3410-12-512-constants(2) paramSetB(2)>>.

Corresponding values of the parameter sets can be found in
Appendix A.1.

5.2.  Twisted Edwards form

This section defines the elliptic curves parameters and identifiers
of the GOST R 34.10-2012 [GOST3410-2012] standard for the case of
elliptic curves that have a representation in Twisted Edwards form
with a prime 256-bit and 512-bit modulus.

A Twisted Edwards curve $E$ over a finite prime field $F_p$, $p > 3$, is an
elliptic curve defined by the equation:

$$e u^2 + v^2 = 1 + d u^2 v^2,$$

where $e$, $d$ are in $F_p$, $ed(e-d) \neq 0$.

A Twisted Edwards curve has an equivalent representation in the
Weierstrass form defined by parameters $a$, $b$. The parameters $a$, $b$, $e$, $d$
are related as follows:

$$a = s^2 - 3 t^2,$$

$$b = 2 t^3 - t s^2,$$

where

$$s = (e - d) / 4,$$

$$t = (e + d) / 6,$$

Coordinate transformation is defined as follows:

$$(u,v) \rightarrow (x,y) = (s(1 + v) / (1 - v) + t, s(1 + v) / ((1 - v) u)),$$

$$(x,y) \rightarrow (u,v) = ((x - t) / y, (x - t - s) / (x - t + s)).$$

5.2.1.  Parameters and identifiers

The parameters for each of the elliptic curve are represented by the
following values which are defined in GOST R 34.10-2012
[GOST3410-2012]:

$p$    the elliptic curve modulus;
a, b  the coefficients of the equation of the elliptic curve in the canonical form;

e, d  the coefficients of the equation of the elliptic curve in the Twisted Edwards form;

m   the order of the elliptic curve group;

q   the order of the subgroups of prime order elliptic curve group;

(x, y) the coordinates of a point P (generator of the prime order group) of the elliptic curve in the canonical form;

(u, v) the coordinates of a point P (generator of the prime order group) of the elliptic curve in the Twisted Edwards form.

Both sets of the parameters are presented as ASN structures of the form:

SEQUENCE {
  p       INTEGER,
  a       INTEGER,
  b       INTEGER,
  e       INTEGER,
  d       INTEGER,
  m       INTEGER,
  q       INTEGER,
  x       INTEGER,
  y       INTEGER,
  u       INTEGER,
  v       INTEGER
}

The parameter sets have the following identifiers:

1. id-tc26-gost-3410-2012-256-paramSetA, <<iso(1) member-body(2) ru(643) rostandart(7) tc26(1) constants(2) sign-constants(1) gost-3410-12-256-constants(1) paramSetA(1)>>;

2. id-tc26-gost-3410-2012-512-paramSetC, <<iso(1) member-body(2) ru(643) rostandart(7) tc26(1) constants(2) sign-constants(1) gost-3410-12-512-constants(2) paramSetC(3)>>.

Corresponding values of the parameter sets can be found in Appendix A.2.
6. Acknowledgments

We thank Valery Smyslov, Igor Ustinov, Basil Dolmatov and Russ Housley for their careful readings and useful comments.
