

A YANG Data Model for IP Management

Abstract

This document defines a YANG data model for management of IP implementations. The data model includes configuration data and state data.

Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 5741.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at <http://www.rfc-editor.org/info/rfc7277>.

1. Introduction

This document defines a YANG [RFC6020] data model for management of IP implementations.

The data model covers configuration of per-interface IPv4 and IPv6 parameters, and mappings of IP addresses to link-layer addresses. It also provides information about which IP addresses are operationally used, and which link-layer mappings exist. Per-interface parameters are added through augmentation of the interface data model defined in [RFC7223].

1.1. Terminology

The following terms are defined in [RFC6241] and are not redefined here:

- o client
- o configuration data
- o server
- o state data

The following terms are defined in [RFC6020] and are not redefined here:

- o augment
- o data model
- o data node

The terminology for describing YANG data models is found in [RFC6020].

1.2. Tree Diagrams

A simplified graphical representation of the data model is used in this document. The meaning of the symbols in these diagrams is as follows:

- o Brackets "[" and "]" enclose list keys.
- o Abbreviations before data node names: "rw" means configuration data (read-write), and "ro" means state data (read-only).
- o Symbols after data node names: "?" means an optional node, "!" means a presence container, and "*" denotes a list and leaf-list.
- o Parentheses enclose choice and case nodes, and case nodes are also marked with a colon (":").
- o Ellipsis ("...") stands for contents of subtrees that are not shown.

2. IP Data Model

This document defines the YANG module "ietf-ip", which augments the "interface" and "interface-state" lists defined in the "ietf-interfaces" module [RFC7223] with IP-specific data nodes, and also adds IP-specific state data.

The data model has the following structure for IP configuration per interface:

```

+--rw if:interfaces
  +--rw if:interface* [name]
    ...
  +--rw ipv4!
    | +--rw enabled?                boolean
    | +--rw forwarding?            boolean
    | +--rw mtu?                   uint16
    | +--rw address* [ip]
    | | +--rw ip                   inet:ipv4-address-no-zone
    | | +--rw (subnet)
    | | | +--:(prefix-length)
    | | | | +--rw ip:prefix-length?  uint8
    | | | +--:(netmask)
    | | | | +--rw ip:netmask?        yang:dotted-quad
    | +--rw neighbor* [ip]
    | | +--rw ip                   inet:ipv4-address-no-zone
    | | +--rw link-layer-address    yang:phys-address
  +--rw ipv6!
    | +--rw enabled?                boolean
    | +--rw forwarding?            boolean
    | +--rw mtu?                   uint32
    | +--rw address* [ip]
    | | +--rw ip                   inet:ipv6-address-no-zone
    | | +--rw prefix-length        uint8
    | +--rw neighbor* [ip]
    | | +--rw ip                   inet:ipv6-address-no-zone
    | | +--rw link-layer-address    yang:phys-address
    +--rw dup-addr-detect-transmits? uint32
    +--rw autoconf
      +--rw create-global-addresses?  boolean
      +--rw create-temporary-addresses? boolean
      +--rw temporary-valid-lifetime?  uint32
      +--rw temporary-preferred-lifetime? uint32

```

The data model defines two configuration containers per interface -- "ipv4" and "ipv6", representing the IPv4 and IPv6 address families. In each container, there is a leaf "enabled" that controls whether or not the address family is enabled on that interface, and a leaf "forwarding" that controls whether or not IP packet forwarding for the address family is enabled on the interface. In each container, there is also a list of configured addresses, and a list of configured mappings from IP addresses to link-layer addresses.

The data model has the following structure for IP state per interface:

```

+--ro if:interfaces-state
  +--ro if:interface* [name]
    ...
    +--ro ipv4!
      +--ro forwarding?   boolean
      +--ro mtu?          uint16
      +--ro address* [ip]
        +--ro ip          inet:ipv4-address-no-zone
        +--ro (subnet)?
          +--:(prefix-length)
            +--ro prefix-length?  uint8
          +--:(netmask)
            +--ro netmask?        yang:dotted-quad
        +--ro origin?        ip-address-origin
      +--ro neighbor* [ip]
        +--ro ip            inet:ipv4-address-no-zone
        +--ro link-layer-address? yang:phys-address
        +--ro origin?      neighbor-origin
    +--ro ipv6!
      +--ro forwarding?   boolean
      +--ro mtu?          uint32
      +--ro address* [ip]
        +--ro ip          inet:ipv6-address-no-zone
        +--ro prefix-length  uint8
        +--ro origin?      ip-address-origin
        +--ro status?      enumeration
      +--ro neighbor* [ip]
        +--ro ip            inet:ipv6-address-no-zone
        +--ro link-layer-address? yang:phys-address
        +--ro origin?      neighbor-origin
        +--ro is-router?   empty
        +--ro state?      enumeration

```

The data model defines two state containers per interface -- "ipv4" and "ipv6", representing the IPv4 and IPv6 address families. In each container, there is a leaf "forwarding" that indicates whether or not IP packet forwarding is enabled on that interface. In each container, there is also a list of all addresses in use and a list of known mappings from IP addresses to link-layer addresses.

3. Relationship to the IP-MIB

If the device implements the IP-MIB [RFC4293], each entry in the "ipv4/address" and "ipv6/address" lists is mapped to one `ipAddressEntry`, where the `ipAddressIfIndex` refers to the "address" entry's interface.

The IP-MIB defines objects to control IPv6 Router Advertisement messages. The corresponding YANG data nodes are defined in [ROUTING-MGMT].

The entries in "ipv4/neighbor" and "ipv6/neighbor" are mapped to `ipNetToPhysicalTable`.

The following tables list the YANG data nodes with corresponding objects in the IP-MIB.

YANG data node in /if:interfaces/if:interface	IP-MIB object
ipv4/enabled	<code>ipv4InterfaceEnableStatus</code>
ipv4/address	<code>ipAddressEntry</code>
ipv4/address/ip	<code>ipAddressAddrType</code> <code>ipAddressAddr</code>
ipv4/neighbor	<code>ipNetToPhysicalEntry</code>
ipv4/neighbor/ip	<code>ipNetToPhysicalNetAddressType</code> <code>ipNetToPhysicalNetAddress</code>
ipv4/neighbor/link-layer-address	<code>ipNetToPhysicalPhysAddress</code>
ipv6/enabled	<code>ipv6InterfaceEnableStatus</code>
ipv6/forwarding	<code>ipv6InterfaceForwarding</code>
ipv6/address	<code>ipAddressEntry</code>
ipv6/address/ip	<code>ipAddressAddrType</code> <code>ipAddressAddr</code>
ipv6/neighbor	<code>ipNetToPhysicalEntry</code>
ipv6/neighbor/link-layer-address	<code>ipNetToPhysicalPhysAddress</code>
ipv6/neighbor/origin	<code>ipNetToPhysicalType</code>

YANG Interface Configuration Data Nodes and Related IP-MIB Objects

YANG data node in /if:interfaces-state/if:interface	IP-MIB object
ipv4	ipv4InterfaceEnableStatus
ipv4/address	ipAddressEntry
ipv4/address/ip	ipAddressAddrType ipAddressAddr
ipv4/address/origin	ipAddressOrigin
ipv4/neighbor	ipNetToPhysicalEntry
ipv4/neighbor/ip	ipNetToPhysicalNetAddressType ipNetToPhysicalNetAddress
ipv4/neighbor/link-layer-address	ipNetToPhysicalPhysAddress
ipv4/neighbor/origin	ipNetToPhysicalType
ipv6	ipv6InterfaceEnableStatus
ipv6/forwarding	ipv6InterfaceForwarding
ipv6/address	ipAddressEntry
ipv6/address/ip	ipAddressAddrType ipAddressAddr
ipv6/address/origin	ipAddressOrigin
ipv6/address/status	ipAddressStatus
ipv6/neighbor	ipNetToPhysicalEntry
ipv6/neighbor/ip	ipNetToPhysicalNetAddressType ipNetToPhysicalNetAddress
ipv6/neighbor/link-layer-address	ipNetToPhysicalPhysAddress
ipv6/neighbor/origin	ipNetToPhysicalType
ipv6/neighbor/state	ipNetToPhysicalState

YANG Interface State Data Nodes and Related IP-MIB Objects

4. IP Management YANG Module

This module imports typedefs from [RFC6991] and [RFC7223], and it references [RFC0791], [RFC0826], [RFC2460], [RFC4861], [RFC4862], [RFC4941], and [RFC7217].

5. IANA Considerations

This document registers a URI in the "IETF XML Registry" [RFC3688]. Following the format in RFC 3688, the following registration has been made.

URI: urn:ietf:params:xml:ns:yang:ietf-ip

Registrant Contact: The NETMOD WG of the IETF.

XML: N/A; the requested URI is an XML namespace.

This document registers a YANG module in the "YANG Module Names" registry [RFC6020].

Name: ietf-ip
Namespace: urn:ietf:params:xml:ns:yang:ietf-ip
Prefix: ip
Reference: RFC 7277

6. Security Considerations

The YANG module defined in this memo is designed to be accessed via the NETCONF protocol [RFC6241]. The lowest NETCONF layer is the secure transport layer and the mandatory-to-implement secure transport is SSH [RFC6242]. The NETCONF access control model [RFC6536] provides the means to restrict access for particular NETCONF users to a pre-configured subset of all available NETCONF protocol operations and content.

There are a number of data nodes defined in the YANG module which are writable/creatable/deletable (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., edit-config) to these data nodes without proper protection can have a negative effect on network operations. These are the subtrees and data nodes and their sensitivity/vulnerability:

ipv4/enabled and ipv6/enabled: These leafs are used to enable or disable IPv4 and IPv6 on a specific interface. By enabling a protocol on an interface, an attacker might be able to create an unsecured path into a node (or through it if routing is also enabled). By disabling a protocol on an interface, an attacker might be able to force packets to be routed through some other interface or deny access to some or all of the network via that protocol.

ipv4/address and ipv6/address: These lists specify the configured IP addresses on an interface. By modifying this information, an attacker can cause a node to either ignore messages destined to it or accept (at least at the IP layer) messages it would otherwise ignore. The use of filtering or security associations may reduce the potential damage in the latter case.

ipv4/forwarding and ipv6/forwarding: These leafs allow a client to enable or disable the forwarding functions on the entity. By disabling the forwarding functions, an attacker would possibly be able to deny service to users. By enabling the forwarding functions, an attacker could open a conduit into an area. This might result in the area providing transit for packets it shouldn't, or it might allow the attacker access to the area, bypassing security safeguards.

ipv6/autoconf: The leafs in this branch control the autoconfiguration of IPv6 addresses and, in particular, whether or not temporary addresses are used. By modifying the corresponding leafs, an attacker might impact the addresses used by a node and thus indirectly the privacy of the users using the node.

ipv4/mtu and ipv6/mtu: Setting these leafs to very small values can be used to slow down interfaces.

7. Acknowledgments

The author wishes to thank Jeffrey Lange, Ladislav Lhotka, Juergen Schoenwaelder, and Dave Thaler for their helpful comments.
