OSPF Version 2 Management Information Base

Status of this Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in TCP/IP-based internets. In particular, it defines objects for managing the Open Shortest Path First Routing Protocol.

Table of Contents

1. The SNMPv2 Network Management Framework	2
1.1 Object Definitions	3
2. Overview	3
2.1 Changes from RFC 1253	3
2.2 Textual Conventions	6
2.3 Structure of MIB	6
2.3.1 General Variables	6
2.3.2 Area Data Structure and Area Stub Metric Table	7
2.3.3 Link State Database and External Link State Database	7
2.3.4 Address Table and Host Tables	7
2.3.5 Interface and Interface Metric Tables	7
2.3.6 Virtual Interface Table	7
2.3.7 Neighbor and Virtual Neighbor Tables	7
2.4 Conceptual Row Creation	7
2.5 Default Configuration	8
3. Definitions	10
3.1 OSPF General Variables	13
3.2 OSPF Area Table	17

3.3 OSPF Area Default Metrics	21
3.4 OSPF Link State Database	25
3.5 OSPF Address Range Table	27
3.6 OSPF Host Table	29
3.7 OSPF Interface Table	32
3.8 OSPF Interface Metrics	39
3.9 OSPF Virtual Interface Table	42
3.10 OSPF Neighbor Table	46
3.11 OSPF Virtual Neighbor Table	51
3.12 OSPF External Link State Database	54
3.13 OSPF Route Table Use	57
3.14 OSPF Area Aggregate Table	58
4. OSPF Traps	66
4.1 Format Of Trap Definitions	67
4.2 Approach	67
4.3 Ignoring Initial Activity	67
4.4 Throttling Traps	67
4.5 One Trap Per OSPF Event	68
4.6 Polling Event Counters	68
5. OSPF Trap Definitions	69
5.1 Trap Support Objects	69
5.2 Traps	71
6. Acknowledgements	78
7. References	78
8. Security Considerations	80
9. Authors' Addresses	80

1. The SNMPv2 Network Management Framework

The SNMPv2 Network Management Framework consists of four major components. They are:

- o RFC 1441 which defines the SMI, the mechanisms used for describing and naming objects for the purpose of management.
- o STD 17, RFC 1213 defines MIB-II, the core set of managed objects for the Internet suite of protocols.
- o RFC 1445 which defines the administrative and other architectural aspects of the framework.
- o RFC 1448 which defines the protocol used for network access to managed objects.

The Framework permits new objects to be defined for the purpose of experimentation and evaluation.

1.1. Object Definitions

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. Objects in the MIB are defined using the subset of Abstract Syntax Notation One (ASN.1) defined in the SMI. In particular, each object object type is named by an OBJECT IDENTIFIER, an administratively assigned name. The object type together with an object instance serves to uniquely identify a specific instantiation of the object. For human convenience, we often use a textual string, termed the descriptor, to refer to the object type.

2. Overview

2.1. Changes from RFC 1253

The changes from RFC 1253 are the following:

- (1) The textual convention PositiveInteger was changed from 1...'FFFFFFFFFF'h to 1...'7FFFFFFF'h at the request of Marshall Rose.
- (2) The textual convention TOSType was changed to reflect the TOS values defined in the Router Requirements Draft, and in accordance with the IP Forwarding Table MIB's values.
- (3) The names of some objects were changed, conforming to the convention that an acronym (for example, LSA) is a single word ("Lsa") in most SNMP names.
- (4) textual changes were made to make the MIB readable by Dave Perkins' SMIC MIB Compiler in addition to Mosy. This involved changing the case of some characters in certain names and removing the DEFVAL clauses for Counters.
- (5) The variables ospfAreaStatus and ospfIfStatus were added, having been overlooked in the original MIB.
- (6) The range of the variable ospfLsdbType was extended to include multicastLink (Group-membership LSA) and nssaExternalLink (NSSA LSA).
- (7) The variable ospfIfMetricMetric was renamed ospfIfMetricValue, and the following text was removed from its description:
"The value FFFF is distinguished to mean 'no route via

this TOS'."

- (8) The variable ospfNbmaNbrPermanence was added, with the values 'dynamic' and 'permanent'; by this means, dynamically learned and configured neighbors can be distinguished.
- (9) The DESCRIPTION of the variable ospfNbrIpAddr was changed from

"The IP address of this neighbor."

to

"The IP address this neighbor is using in its IP Source Address. Note that, on addressless links, this will not be 0.0.0.0, but the address of another of the neighbor's interfaces."

This is by way of clarification and does not change the specification.
- (10) The OSPF External Link State Database was added. The OSPF Link State Database used to display all LSAs stored; in this MIB, it displays all but the AS External LSAs. This is because there are usually a large number of External LSAs, and they are replicated in all non-Stub Areas.
- (11) The variable ospfAreaSummary was added to control the import of summary LSAs into stub areas. If it is noAreaSummary (default) the router will neither originate nor propagate summary LSAs into the stub area. It will rely entirely on its default route. If it is sendAreaSummary, the router will both summarize and propagate summary LSAs.
- (12) The general variables ospfExtLsdbLimit and ExitOverflowInterval were introduced to help handle LSDB overflow.
- (13) The use of the IP Forwarding Table is defined.

- (14) The ospfAreaRangeTable was obsoleted and replaced with the ospfAreaAggregateTable to accommodate two additional indexes. The ospfAreaAggregateEntry keys now include a LsdbType (which can be used to differentiate between the traditional type-3 Aggregates and NSSA Aggregates) and an

ospfAreaAggregateMask (which will more clearly express the range).

- (15) The variable ospfAreaAggregateEffect was added. This permits the network manager to hide a subnet within an area.
- (16) Normally, the border router of a stub area advertises a default route as an OSPF network summary. An NSSA border router will generate a type-7 LSA indicating a default route, and import it into the NSSA. ospfStubMetricType (ospf internal, type 1 external, or type 2 external) indicates the type of the default metric advertised.
- (17) ospfMulticastExtensions is added to the OSPF General Group. This indicates the router's ability to forward IP multicast (Class D) datagrams.
- (18) ospfIfMulticastForwarding is added to the Interface Group. It indicates whether, and if so, how, multicasts should be forwarded on the interface.
- (19) The MIB is converted to SNMP Version 2. Beyond simple text changes and the addition of the MODULE-IDENTITY and MODULE-COMPLIANCE macros, this involved trading the TruthValue Textual Convention for SNMP Version 2's, which has the same values, and trading the Validation Textual Convention for SNMP Version 2's RowStatus.
- (20) ospfAuthType (area authentication type) was changed to an interface authentication type to match the key. It also has an additional value, to indicate the use of MD5 for authentication.
- (21) ospfIfIntfType has a new value, pointToMultipoint.
- (22) ospfIfDemand (read/write) is added, to permit control of Demand OSPF features.
- (23) ospfNbrHelloSuppressed and ospfVirtNbrHelloSuppressed were added, (read only). They indicate whether Hellos are being suppressed to the neighbor.
- (24) ospfDemandExtensions was added to indicate whether the Demand OSPF extensions have been implemented, and to disable them if appropriate.

2.2. Textual Conventions

Several new data types are introduced as a textual convention in this MIB document. These textual conventions enhance the readability of the specification and can ease comparison with other specifications if appropriate. It should be noted that the introduction of the these textual conventions has no effect on either the syntax nor the semantics of any managed objects. The use of these is merely an artifact of the explanatory method used. Objects defined in terms of one of these methods are always encoded by means of the rules that define the primitive type. Hence, no changes to the SMI or the SNMP are necessary to accommodate these textual conventions which are adopted merely for the convenience of readers and writers in pursuit of the elusive goal of clear, concise, and unambiguous MIB documents.

The new data types are AreaID, RouterID, TOSType, Metric, BigMetric, Status, PositiveInteger, HelloRange, UpToMaxAge, InterfaceIndex, and DesignatedRouterPriority.

2.3. Structure of MIB

The MIB is composed of the following sections:

```
General Variables
Area Data Structure
Area Stub Metric Table
Link State Database
Address Range Table
Host Table
Interface Table
Interface Metric Table
Virtual Interface Table
Neighbor Table
Virtual Neighbor Table
External Link State Database
Aggregate Range Table
```

There exists a separate MIB for notifications ("traps"), which is entirely optional.

2.3.1. General Variables

The General Variables are about what they sound like; variables which are global to the OSPF Process.

2.3.2. Area Data Structure and Area Stub Metric Table

The Area Data Structure describes the OSPF Areas that the router participates in. The Area Stub Metric Table describes the metrics advertised into a stub area by the default router(s).

2.3.3. Link State Database and External Link State Database

The Link State Database is provided primarily to provide detailed information for network debugging.

2.3.4. Address Table and Host Tables

The Address Range Table and Host Table are provided to view configured Network Summary and Host Route information.

2.3.5. Interface and Interface Metric Tables

The Interface Table and the Interface Metric Table together describe the various IP interfaces to OSPF. The metrics are placed in separate tables in order to simplify dealing with multiple types of service, and to provide flexibility in the event that the IP TOS definition is changed in the future. A Default Value specification is supplied for the TOS 0 (default) metric.

2.3.6. Virtual Interface Table

Likewise, the Virtual Interface Table describe virtual links to the OSPF Process.

2.3.7. Neighbor and Virtual Neighbor Tables

The Neighbor Table and the Virtual Neighbor Table describe the neighbors to the OSPF Process.

2.4. Conceptual Row Creation

For the benefit of row-creation in "conceptual" (see [9]) tables, DEFVAL (Default Value) clauses are included in the definitions in section 3, suggesting values which an agent should use for instances of variables which need to be created due to a Set-Request, but which are not specified in the Set-Request. DEFVAL clauses have not been specified for some objects which are read-only, implying that they are zeroed upon row creation. These objects are of the SYNTAX Counter32 or Gauge32.

For those objects not having a DEFVAL clause, both management stations and agents should heed the Robustness Principle of the

Internet (see RFC-791):

"be liberal in what you accept, conservative in what you send"

That is, management stations should include as many of these columnar objects as possible (e.g., all read-write objects) in a Set-Request when creating a conceptual row; agents should accept a Set-Request with as few of these as they need (e.g., the minimum contents of a row creating SET consists of those objects for which, as they cannot be intuited, no default is specified.).

There are numerous read-write objects in this MIB, as it is designed for SNMP management of the protocol, not just SNMP monitoring of its state. However, in the absence of a standard SNMP Security architecture, it is acceptable for implementations to implement these as read-only with an alternative interface for their modification.

2.5. Default Configuration

OSPF is a powerful routing protocol, equipped with features to handle virtually any configuration requirement that might reasonably be found within an Autonomous System. With this power comes a fair degree of complexity, which the sheer number of objects in the MIB will attest to. Care has therefore been taken, in constructing this MIB, to define default values for virtually every object, to minimize the amount of parameterization required in the typical case. That default configuration is as follows:

Given the following assumptions:

- IP has already been configured
- The ifTable has already been configured
- ifSpeed is estimated by the interface drivers
- The OSPF Process automatically discovers all IP Interfaces and creates corresponding OSPF Interfaces
- The TOS 0 metrics are autonomously derived from ifSpeed
- The OSPF Process automatically creates the Areas required for the Interfaces

The simplest configuration of an OSPF process requires that:

- The OSPF Process be Enabled.

This can be accomplished with a single SET:

```
ospfAdminStat := enabled.
```

The configured system will have the following attributes:

- The RouterID will be one of the IP addresses of the device
- The device will be neither an Area Border Router nor an Autonomous System Border Router.
- Every IP Interface, with or without an address, will be an OSPF Interface.
- The AreaID of each interface will be 0.0.0.0, the Backbone.
- Authentication will be disabled
- All Broadcast and Point to Point interfaces will be operational. NBMA Interfaces require the configuration of at least one neighbor.
- Timers on all direct interfaces will be:

Hello Interval:	10 seconds
Dead Timeout:	40 Seconds
Retransmission:	5 Seconds
Transit Delay:	1 Second
Poll Interval:	120 Seconds

- no direct links to hosts will be configured.
- no addresses will be summarized
- Metrics, being a measure of bit duration, are unambiguous and intelligent.
- No Virtual Links will be configured.

     tions of self-originated link-state advertise-
     ments."
 ::= { ospfGeneralGroup 10 }
```

```

ospfExtLsdbLimit OBJECT-TYPE
  SYNTAX  Integer32 (-1...'7FFFFFFF'h)
  MAX-ACCESS  read-write
  STATUS  current
  DESCRIPTION
    "The maximum number of non-default AS-
     external-LSAs entries that can be stored in the
     link-state database. If the value is -1, then
     there is no limit.

When the number of non-default AS-external-LSAs
in a router's link-state database reaches
ospfExtLsdbLimit, the router enters Overflow-
State. The router never holds more than
ospfExtLsdbLimit non-default AS-external-LSAs
in its database. OspfExtLsdbLimit MUST be set
identically in all routers attached to the OSPF
backbone and/or any regular OSPF area. (i.e.,
OSPF stub areas and NSSAs are excluded)."
DEFVAL { -1 }
 ::= { ospfGeneralGroup 11 }

```

```

ospfMulticastExtensions OBJECT-TYPE
  SYNTAX  Integer32
  MAX-ACCESS  read-write
  STATUS  current
  DESCRIPTION
    "A Bit Mask indicating whether the router is
     forwarding IP multicast (Class D) datagrams
     based on the algorithms defined in the Multi-
     cast Extensions to OSPF.

```

Bit 0, if set, indicates that the router can forward IP multicast datagrams in the router's directly attached areas (called intra-area multicast routing).

Bit 1, if set, indicates that the router can forward IP multicast datagrams between OSPF areas (called inter-area multicast routing).

Bit 2, if set, indicates that the router can forward IP multicast datagrams between Autonomous Systems (called inter-AS multicast routing).

Only certain combinations of bit settings are allowed, namely: 0 (no multicast forwarding is

```

enabled), 1 (intra-area multicasting only), 3
(intra-area and inter-area multicasting), 5
(intra-area and inter-AS multicasting) and 7
(multicasting everywhere). By default, no mul-
ticast forwarding is enabled."
DEFVAL { 0 }
 ::= { ospfGeneralGroup 12 }

ospfExitOverflowInterval OBJECT-TYPE
    SYNTAX  PositiveInteger
    MAX-ACCESS  read-write
    STATUS  current
    DESCRIPTION
        "The number of seconds that, after entering
        OverflowState, a router will attempt to leave
        OverflowState. This allows the router to again
        originate non-default AS-external-LSAs. When
        set to 0, the router will not leave Overflow-
        State until restarted."

-- OSPF Interface Metric Table

-- The Metric Table describes the metrics to be advertised
-- for a specified interface at the various types of service.
-- As such, this table is an adjunct of the OSPF Interface
-- Table.

-- Types of service, as defined by RFC 791, have the ability
-- to request low delay, high bandwidth, or reliable linkage.

-- For the purposes of this specification, the measure of
-- bandwidth

-- Metric = 10^8 / ifSpeed

-- is the default value. For multiple link interfaces, note
-- that ifSpeed is the sum of the individual link speeds.
-- This yields a number having the following typical values:

-- Network Type/bit rate      Metric
--      >= 100 MBPS              1
--      Ethernet/802.3           10
```

```

--      E1                  48
--      T1 (ESF)            65
--      64 KBPS             1562
--      56 KBPS             1785
--      19.2 KBPS           5208
--      9.6 KBPS            10416

-- Routes that are not specified use the default (TOS 0) metric

-- OSPF Use of the CIDR Route Table

```
ospfRouteGroup      OBJECT IDENTIFIER ::= { ospf 13 }

-- The IP Forwarding Table defines a number of objects for use by
-- the routing protocol to externalize its information.  Most of
-- the variables (ipForwardDest, ipForwardMask, ipForwardPolicy,
-- ipForwardNextHop, ipForwardIfIndex, ipForwardType,
-- ipForwardProto, ipForwardAge, and ipForwardNextHopAS) are
-- defined there.

-- Those that leave some discretion are defined here.

-- ipCidrRouteProto is, of course, ospf (13).

-- ipCidrRouteAge is the time since the route was first calculated,
-- as opposed to the time since the last SPF run.

-- ipCidrRouteInfo is an OBJECT IDENTIFIER for use by the routing
-- protocol.  The following values shall be found there depending
-- on the way the route was calculated.
```

```
ospfIntraArea      OBJECT IDENTIFIER ::= { ospfRouteGroup 1 }
ospfInterArea      OBJECT IDENTIFIER ::= { ospfRouteGroup 2 }
ospfExternalType1  OBJECT IDENTIFIER ::= { ospfRouteGroup 3 }
ospfExternalType2  OBJECT IDENTIFIER ::= { ospfRouteGroup 4 }
```

```
-- ipCidrRouteMetric1 is, by definition, the primary routing
-- metric.  Therefore, it should be the metric that route
-- selection is based on.  For intra-area and inter-area routes,
-- it is an OSPF metric.  For External Type 1 (comparable value)
-- routes, it is an OSPF metric plus the External Metric.  For
-- external Type 2 (non-comparable value) routes, it is the
-- external metric.
```

-- ipCidrRouteMetric2 is, by definition, a secondary routing

-- metric. Therefore, it should be the metric that breaks a tie
-- among routes having equal metric1 values and the same
-- calculation rule. For intra-area, inter-area routes, and
-- External Type 1 (comparable value) routes, it is unused. For
-- external Type 2 (non-comparable value) routes, it is the metric
-- to the AS border router.

-- ipCidrRouteMetric3, ipCidrRouteMetric4, and ipCidrRouteMetric5 are
-- unused.

--
-- The OSPF Area Aggregate Table
--
-- This table replaces the OSPF Area Summary Table, being an
-- extension of that for CIDR routers.

4. OSPF Traps

OSPF is an event driven routing protocol, where an event can be a change in an OSPF interface's link-level status, the expiration of an OSPF timer or the reception of an OSPF protocol packet. Many of the actions that OSPF takes as a result of these events will result in a change of the routing topology. As routing topologies become large and complex it is often difficult to locate the source of a topology change or unpredicted routing path by polling a large number of routers. Another approach is to notify a network manager of potentially critical OSPF events with SNMP traps.

This section defines a set of traps, objects and mechanisms to enhance the ability to manage IP internetworks which use OSPF as its IGP. It is an optional but useful extension to the OSPF MIB.

4.1. Format Of Trap Definitions

Section 7 contains contains the trap definitions.

4.2. Approach

The mechanism for sending traps is straight-forward. When an exception event occurs, the application notifies the local agent who sends a trap to the appropriate SNMP management stations. The message includes the trap type and may include a list of trap specific variables. A new object is defined in section 3.2 that will allow a network manager to enable or disable particular OSPF traps. Section 5 gives the trap definitions which includes the variable lists. The router ID of the originator of the trap is included in the variable list so that the network manager may easily determine the source of the trap.

To limit the frequency of OSPF traps, the following additional mechanisms are suggested.

4.3. Ignoring Initial Activity

The majority of critical events occur when OSPF is enabled on a router, at which time the designated router is elected and neighbor adjacencies are formed. During this initial period a potential flood of traps is unnecessary since the events are expected. To avoid unnecessary traps, a router should not originate expected OSPF interface related traps until two of that interface's dead timer intervals have elapsed. The expected OSPF interface traps are ospfIfStateChange, ospfVirtIfStateChange, ospfNbrStateChange, ospfVirtNbrStateChange, ospfTxRetransmit and ospfVirtIfTxRetransmit. Additionally, ospfMaxAgeLsa and ospfOriginateLsa traps should not be originated until two dead timer intervals have elapsed where the dead timer interval used should be the dead timer with the smallest value.

4.4. Throttling Traps

The mechanism for throttling the traps is similar to the mechanism explained in RFC 1224 [11], section 5. The basic idea is that there is a sliding window in seconds and an upper bound on the number of traps that may be generated within this window. Unlike RFC 1224, traps are not sent to inform the network manager that the throttling mechanism has kicked in.

A single window should be used to throttle all OSPF traps types except for the ospfLsdbOverflow and the ospfLsdbApproachingOverflow trap which should not be throttled. For example, if the window time is 3, the upper bound is 3 and the events that would cause trap types 1,3,5 and 7 occur within a 3 second period, the type 7 trap should not be generated.

Appropriate values are 7 traps with a window time of 10 seconds.

4.5. One Trap Per OSPF Event

Several of the traps defined in section 5 are generated as the result of finding an unusual condition while parsing an OSPF packet or a processing a timer event. There may be more than one unusual condition detected while handling the event. For example, a link-state update packet may contain several retransmitted link-state advertisements (LSAs), or a retransmitted database description packet may contain several database description entries. To limit the number of traps and variables, OSPF should generate at most one trap per OSPF event. Only the variables associated with the first unusual condition should be included with the trap. Similarly, if more than one type of unusual condition is encountered while parsing the packet, only the first event will generate a trap.

4.6. Polling Event Counters

Many of the tables in the OSPF MIB contain generalized event counters. By enabling the traps defined in this document a network manager can obtain more specific information about these events. A network manager may want to poll these event counters and enable specific OSPF traps when a particular counter starts increasing abnormally.

The following table shows the relationship between the event counters defined in the OSPF MIB and the trap types defined in section 5.

Counter32	Trap Type
ospfOriginateNewLsas	ospfOriginateLsa
ospfIfEvents	ospfIfStateChange ospfConfigError ospfIfAuthFailure ospfRxBadPacket ospfTxRetransmit
ospfVirtIfEvents	ospfVirtIfStateChange ospfVirtIfConfigError ospfVirtIfAuthFailure

```

ospfVirtIfRxBadPacket
ospfVirtIfTxRetransmit
ospfNbrEvents
ospfVirtNbrEvents
ospfExternLSACount
ospfExternLSACount
ospfNbrStateChange
ospfVirtNbrStateChange
ospfLsdbApproachingOverflow
ospfLsdbOverflow

```

ospfVirtNbrStateChange NOTIFICATION-TYPE
OBJECTS {
    ospfRouterId, -- The originator of the trap
    ospfVirtNbrArea,
    ospfVirtNbrRtrId,
    ospfVirtNbrState -- The new state
}
STATUS          current
DESCRIPTION
    "An ospfIfStateChange trap signifies that there has been a change in the state of an OSPF virtual neighbor. This trap should be generated when the neighbor state regresses (e.g., goes from Attempt or Full to 1-Way or Down) or progresses to a terminal state (e.g., Full)."
 ::= { ospfTraps 3 }

```

```

ospfIfConfigError NOTIFICATION-TYPE
OBJECTS {
    ospfRouterId, -- The originator of the trap
    ospfIfIpAddress,
    ospfAddressLessIf,
    ospfPacketSrc, -- The source IP address
    ospfConfigErrorType, -- Type of error
    ospfPacketType
}
STATUS          current
DESCRIPTION
    "An ospfIfConfigError trap signifies that a
     packet has been received on a non-virtual in-
     terface from a router whose configuration
     parameters conflict with this router's config-
     uration parameters. Note that the event op-
     tionMismatch should cause a trap only if it
     prevents an adjacency from forming."
::= { ospfTraps 4 }

```

```

ospfVirtIfConfigError NOTIFICATION-TYPE
OBJECTS {
    ospfRouterId, -- The originator of the trap
    ospfVirtIfAreaId,
    ospfVirtIfNeighbor,
    ospfConfigErrorType, -- Type of error
    ospfPacketType
}
STATUS          current
DESCRIPTION
    "An ospfConfigError trap signifies that a pack-
     et has been received on a virtual interface
     from a router whose configuration parameters
     conflict with this router's configuration
     parameters. Note that the event optionMismatch
     should cause a trap only if it prevents an ad-
     jacency from forming."
::= { ospfTraps 5 }

```

```

ospfIfAuthFailure NOTIFICATION-TYPE
OBJECTS {

OBJECTS {
        ospfRouterId, -- The originator of the trap
        ospfVirtIfAreaId,
        ospfVirtIfNeighbor,
        ospfConfigErrorType, -- authTypeMismatch or
                           -- authFailure
        ospfPacketType
}
STATUS           current
DESCRIPTION
    "An ospfVirtIfAuthFailure trap signifies that a
     packet has been received on a virtual interface
     from a router whose authentication key or au-
     thentication type conflicts with this router's
     authentication key or authentication type."
::= { ospfTraps 7 }

ospfIfRxBadPacket NOTIFICATION-TYPE
OBJECTS {
        ospfRouterId, -- The originator of the trap
        ospfIfIpAddress,
        ospfAddressLessIf,
        ospfPacketSrc, -- The source IP address
        ospfPacketType
}
STATUS           current
DESCRIPTION
    "An ospfIfRxBadPacket trap signifies that an
     OSPF packet has been received on a non-virtual
     interface that cannot be parsed."
::= { ospfTraps 8 }

```

```

ospfVirtIfRxBadPacket NOTIFICATION-TYPE
OBJECTS {
    ospfRouterId, -- The originator of the trap
    ospfVirtIfAreaId,
    ospfVirtIfNeighbor,
    ospfPacketType
}
STATUS           current
DESCRIPTION
  "An ospfRxBadPacket trap signifies that an OSPF
  packet has been received on a virtual interface
  that cannot be parsed."
 ::= { ospfTraps 9 }

ospfTxRetransmit NOTIFICATION-TYPE
OBJECTS {
    ospfRouterId, -- The originator of the trap
    ospfIfIpAddress,
    ospfAddressLessIf,
    ospfNbrRtrId, -- Destination
    ospfPacketType,
    ospfLsdbType,
    ospfLsdbLsid,
    ospfLsdbRouterId
}
STATUS           current
DESCRIPTION
  "An ospfTxRetransmit trap signifies than an
  OSPF packet has been retransmitted on a non-
  virtual interface. All packets that may be re-
  transmitted are associated with an LSDB entry.
  The LS type, LS ID, and Router ID are used to
  identify the LSDB entry."
 ::= { ospfTraps 10 }

ospfVirtIfTxRetransmit NOTIFICATION-TYPE
OBJECTS {
    ospfRouterId, -- The originator of the trap
    ospfVirtIfAreaId,
    ospfVirtIfNeighbor,
    ospfPacketType,
    ospfLsdbType,
    ospfLsdbLsid,
    ospfLsdbRouterId
}
STATUS           current

```

DESCRIPTION

"An ospfTxRetransmit trap signifies than an OSPF packet has been retransmitted on a virtual interface. All packets that may be retransmitted are associated with an LSDB entry. The LS type, LS ID, and Router ID are used to identify the LSDB entry."

```
::= { ospfTraps 11 }
```

ospfOriginateLsa NOTIFICATION-TYPE

OBJECTS {

ospfRouterId, -- The originator of the trap
 ospfLsdbAreaId, -- 0.0.0.0 for AS Externals
 ospfLsdbType,
 ospfLsdbLsid,
 ospfLsdbRouterId

```
}
```

STATUS current

DESCRIPTION

"An ospfOriginateLsa trap signifies that a new LSA has been originated by this router. This trap should not be invoked for simple refreshes of LSAs (which happens every 30 minutes), but instead will only be invoked when an LSA is (re)originated due to a topology change. Additionally, this trap does not include LSAs that are being flushed because they have reached MaxAge."

```
::= { ospfTraps 12 }
```

ospfMaxAgeLsa NOTIFICATION-TYPE

OBJECTS {

ospfRouterId, -- The originator of the trap
 ospfLsdbAreaId, -- 0.0.0.0 for AS Externals
 ospfLsdbType,
 ospfLsdbLsid,
 ospfLsdbRouterId

```
}
```

STATUS current

DESCRIPTION

"An ospfMaxAgeLsa trap signifies that one of the LSA in the router's link-state database has aged to MaxAge."

```
::= { ospfTraps 13 }
```

```

ospfLsdbOverflow NOTIFICATION-TYPE
OBJECTS {
    ospfRouterId, -- The originator of the trap
    ospfExtLsdbLimit
}
STATUS          current
DESCRIPTION
  "An ospfLsdbOverflow trap signifies that the
   number of LSAs in the router's link-state data-
   base has exceeded ospfExtLsdbLimit."
 ::= { ospfTraps 14 }

ospfLsdbApproachingOverflow NOTIFICATION-TYPE
OBJECTS {
    ospfRouterId, -- The originator of the trap
    ospfExtLsdbLimit
}
STATUS          current
DESCRIPTION
  "An ospfLsdbApproachingOverflow trap signifies
   that the number of LSAs in the router's link-
   state database has exceeded ninety percent of
   ospfExtLsdbLimit."
 ::= { ospfTraps 15 }

-- conformance information
