Indicating Character Encoding and Language for HTTP Header Field Parameters

Abstract

By default, header field values in Hypertext Transfer Protocol (HTTP) messages cannot easily carry characters outside the US-ASCII coded character set. RFC 2231 defines an encoding mechanism for use in parameters inside Multipurpose Internet Mail Extensions (MIME) header field values. This document specifies an encoding suitable for use in HTTP header fields that is compatible with a simplified profile of the encoding defined in RFC 2231.

This document obsoletes RFC 5987.

Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 7841.

1. Introduction

Use of characters outside the US-ASCII coded character set
([RFC0020]) in HTTP header fields ([RFC7230]) is non-trivial:

- The HTTP specification discourages use of non-US-ASCII characters
  in field values, placing them into the "obs-text" Augmented
  Backus-Naur Form (ABNF) production ([RFC7230], Section 3.2).

- Furthermore, it stays silent about default character encoding
  schemes for field values, so any use of non-US-ASCII characters
  would need to be specific to the field definition or would require
  some other kind of out-of-band information.

- Finally, some APIs assume a default character encoding scheme in
  order to map from the octet sequences (obtained from the HTTP
  message) to character sequences: for instance, the XMLHttpRequest
  API ([XMLHttpRequest]) uses the Interface Definition Language type
  "ByteString", effectively resulting in the ISO-8859-1 character
  encoding scheme ([ISO-8859-1]) being used.
On the other hand, RFC 2231 defines an encoding mechanism for parameters inside MIME header fields ([RFC2231]), which, as opposed to HTTP messages, do need to be sent over non-binary transports. This document specifies an encoding suitable for use in HTTP header fields that is compatible with a simplified profile of the encoding defined in RFC 2231. It can be applied to any HTTP header field that uses the common "parameter" ("name=value") syntax.

This document obsoletes [RFC5987] and moves it to "Historic" status; the changes are summarized in Appendix A.

Note: In the remainder of this document, RFC 2231 is only referenced for the purpose of explaining the choice of features that were adopted; therefore, they are purely informative.

Note: This encoding does not apply to message payloads transmitted over HTTP, such as when using the media type "multipart/form-data" ([RFC7578]).

2. Notational Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

This specification uses the ABNF notation defined in [RFC5234]. The following core rules are included by reference, as defined in [RFC5234], Appendix B.1: ALPHA (letters), DIGIT (decimal 0-9), HEXDIG (hexadecimal 0-9/A-F/a-f), and LWSP (linear whitespace).

This specification uses terminology defined in [RFC6365], namely: "character encoding scheme" (abbreviated to "character encoding" below), "charset", and "coded character set".

Note that this differs from RFC 2231, which uses the term "character set" for "character encoding scheme".

3. Comparison to RFC 2231 and Definition of the Encoding

RFC 2231 defines several extensions to MIME. The sections below discuss if and how they apply to HTTP header fields.

In short:

- Parameter Continuations aren’t needed (Section 3.1),
Character Encoding and Language Information are useful, therefore
a simple subset is specified (Section 3.2), and

Language Specifications in Encoded Words aren’t needed
(Section 3.3).

3.1. Parameter Continuations

Section 3 of [RFC2231] defines a mechanism that deals with the length
limitations that apply to MIME headers. These limitations do not
apply to HTTP ([RFC7231], Appendix A.6).

Thus, parameter continuations are not part of the encoding defined by
this specification.

3.2. Parameter Value Character Encoding and Language Information

Section 4 of [RFC2231] specifies how to embed language information
into parameter values and also how to encode non-ASCII characters,
dealing with restrictions both in MIME and HTTP header field
parameters.

However, RFC 2231 does not specify a mandatory-to-implement character
encoding, making it hard for senders to decide which encoding to use.
Thus, recipients implementing this specification MUST support the
"UTF-8" character encoding [RFC3629].

Furthermore, RFC 2231 allows the character encoding information to be
left out. The encoding defined by this specification does not allow
that.

3.2.1. Definition

The presence of extended parameter values is usually indicated by a
parameter name ending in an asterisk character. However, note that
this is just a convention, and that the extended parameter values
need to be explicitly specified in the definition of the header field
using this extension (see Section 4).

The ABNF for extended parameter values is specified below:
ext-value = charset "'" [ language ] "'" value-chars
               ; like RFC 2231’s <extended-initial-value>
               ; (see [RFC2231], Section 7)

charset    = "UTF-8" / mime-charset

mime-charset = 1*mime-charsetc
mime-charsetc = ALPHA / DIGIT
               / "!" / "#" / "$" / "&" / "'" / "('" / "(''
               / "(" / ")" / "="
               ; as <mime-charset> in Section 2.3 of [RFC2978]
               ; except that the single quote is not included
               ; SHOULD be registered in the IANA charset registry

language  = <Language-Tag, see [RFC5646], Section 2.1>

value-chars = *( pct-encoded / attr-char )
pct-encoded = "%%" HEXDIG HEXDIG
               ; see [RFC3986], Section 2.1

attr-char  = ALPHA / DIGIT
               / "!" / "#" / "$" / "&" / "('" / "(''
               / "(" / ")" / "="
               ; token except ( "*" / "'" / "&" )

The value part of an extended parameter (ext-value) is a token that
consists of three parts:

1. the REQUIRED character encoding name (charset),
2. the OPTIONAL language information (language), and
3. a character sequence representing the actual value (value-chars),
   separated by single quote characters.

Note that both character encoding names and language tags are
restricted to the US-ASCII coded character set and are matched case-
insensitively (see Section 2.3 of [RFC2978] and Section 2.1.1 of
[RFC5646]).

Inside the value part, characters not contained in attr-char are
encoded into an octet sequence using the specified character
encoding. That octet sequence is then percent-encoded as specified
in Section 2.1 of [RFC3986].
Producers MUST use the "UTF-8" ([RFC3629]) character encoding. Extension character encodings (mime-charset) are reserved for future use.

Note: Recipients should be prepared to handle encoding errors, such as malformed or incomplete percent escape sequences, or non-decodable octet sequences, in a robust manner. This specification does not mandate any specific behavior; for instance, the following strategies are all acceptable:

* ignoring the parameter,
* stripping a non-decodable octet sequence, and
* substituting a non-decodable octet sequence by a replacement character, such as the Unicode character U+FFFD (Replacement Character).

### 3.2.2. Historical Notes

The RFC 7230 token production ([RFC7230], Section 3.2.6) differs from the production used in RFC 2231 (imported from Section 5.1 of [RFC2045]) in that curly braces (i.e., "{" and "}") are excluded. Thus, these two characters are excluded from the attr-char production as well.

The <mime-charset> ABNF defined here differs from the one in Section 2.3 of [RFC2978] in that it does not allow the single quote character (see also RFC Errata ID 1912 [Err1912]). In practice, no character encoding names using that character have been registered at the time of this writing.

For backwards compatibility with RFC 2231, the encoding defined by this specification deviates from common parameter syntax in that the quoted-string notation is not allowed. Implementations using generic parser components might not be able to detect the use of quoted-string notation and thus might accept that format, although invalid, as well.

[RFC5987] did require support for ISO-8859-1 ([ISO-8859-1]), too; for compatibility with legacy code, recipients are encouraged to support this encoding as well.

### 3.2.3. Examples

Non-extended notation, using "token":

foo: bar; title=Economy
Non-extended notation, using "quoted-string":

    foo: bar; title="US-$ rates"

Extended notation, using the Unicode character U+00A3 ("£", POUND SIGN):

    foo: bar; title*=utf-8'en'\%C2\xA3%20rates

Note: The Unicode pound sign character U+00A3 was encoded into the octet sequence C2 A3 using the UTF-8 character encoding, and then percent-encoded. Also, note that the space character was encoded as %20, as it is not contained in attr-char.

Extended notation, using the Unicode characters U+00A3 ("£", POUND SIGN) and U+20AC ("€", EURO SIGN):

    foo: bar; title*=UTF-8''\%c2\xA3%20and%20\%e2\%82\%ac%20rates

Note: The Unicode pound sign character U+00A3 was encoded into the octet sequence C2 A3 using the UTF-8 character encoding, and then percent-encoded. Likewise, the Unicode euro sign character U+20AC was encoded into the octet sequence E2 82 AC, and then percent-encoded. Also note that HEXDIG allows both lowercase and uppercase characters, so recipients must understand both, and that the language information is optional, while the character encoding is not.

3.3. Language Specification in Encoded Words

Section 5 of [RFC2231] extends the encoding defined in [RFC2047] to also support language specification in encoded words. RFC 2616, the now-obsolete HTTP/1.1 specification, did refer to RFC 2047 ([RFC2616], Section 2.2). However, it wasn’t clear to which header field it applied. Consequently, the current revision of the HTTP/1.1 specification has deprecated use of the encoding forms defined in RFC 2047 (see Section 3.2.4 of [RFC7230]).

Thus, this specification does not include this feature.

4. Guidelines for Usage in HTTP Header Field Definitions

Specifications of HTTP header fields that use the extensions defined in Section 3.2 ought to clearly state that. A simple way to achieve this is to normatively reference this specification and to include the ext-value production into the ABNF for specific header field parameters.
For instance:

```plaintext
title-param = "title" LWSP "=" LWSP value
    / "title*" LWSP "=" LWSP ext-value
```

Note: The Parameter Value Continuation feature defined in Section 3 of [RFC2231] makes it impossible to have multiple instances of extended parameters with identical names, as the processing of continuations would become ambiguous. Thus, specifications using this extension are advised to disallow this case for compatibility with RFC 2231.

Note: This specification does not automatically assign a new interpretation to parameter names ending in an asterisk. As pointed out above, it’s up to the specification for the non-extended parameter to "opt in" to the syntax defined here. That being said, some existing implementations are known to automatically switch to using this notation when a parameter name ends with an asterisk; thus, using parameter names ending in an asterisk for something else is likely to cause interoperability problems.

4.1. When to Use the Extension

Section 4.2 of [RFC2277] requires that protocol elements containing human-readable text be able to carry language information. Thus, the ext-value production ought to always be used when the parameter value is of a textual nature and its language is known.

Furthermore, the extension ought to also be used whenever the parameter value needs to carry characters not present in the US-ASCII coded character set ([RFC0020]); note that it would be unacceptable to define a new parameter that would be restricted to a subset of the Unicode character set.

4.2. Error Handling

Header field specifications need to define whether multiple instances of parameters with identical names are allowed and how they should be processed. This specification suggests that a parameter using the extended syntax takes precedence. This would allow producers to use both formats without breaking recipients that do not understand the extended syntax yet.
Example:

    foo: bar; title="EURO exchange rates";
    title*=utf-8''%e2%82%ac%20exchange%20rates

In this case, the sender provides an ASCII version of the title for legacy recipients, but also includes an internationalized version for recipients understanding this specification -- the latter obviously ought to prefer the new syntax over the old one.

5. Security Considerations

The format described in this document makes it possible to transport non-ASCII characters, and thus enables character "spoofing" scenarios in which a displayed value appears to be something other than it is.

Furthermore, there are known attack scenarios related to decoding UTF-8.

See Section 10 of [RFC3629] for more information on both topics.

In addition, the extension specified in this document makes it possible to transport multiple language variants for a single parameter, and such use might allow spoofing attacks where different language versions of the same parameter are not equivalent. Whether this attack is effective as an attack depends on the parameter specified.

6. IANA Considerations

This document does not require any IANA actions.

7. References

7.1. Normative References

7.2. Informative References

7.2. Informative References

Appendix A.  Changes from RFC 5987

This section summarizes the changes compared to [RFC5987]:

- The document title was changed to "Indicating Character Encoding and Language for HTTP Header Field Parameters".
- The introduction was rewritten to better explain the issues around non-ASCII characters in field values.
- The requirement to support the "ISO-8859-1" encoding was removed.
- This document no longer attempts to redefine a generic "parameter" ABNF (it turned out that there really isn’t a generic definition of parameters in HTTP; for instance, there are subtle differences with respect to whitespace handling).
- A note about defects in error handling in current implementations was removed, as it was no longer accurate.

Appendix B.  Implementation Report

The encoding defined in this document is currently used in four different HTTP header fields:

- "Authentication-Control", defined in [RFC8053],
- "Authorization" (as used in HTTP Digest Authentication, defined in [RFC7616]),
- "Content-Disposition", defined in [RFC6266], and
- "Link", defined in [RFC5988].

As the encoding is a profile/clarification of the one defined in [RFC2231] in 1997, many user agents already supported it for use in "Content-Disposition" when [RFC5987] was published.

Since the publication of [RFC5987], three more popular desktop user agents have added support for this encoding; see <http://purl.org/NET/http/content-disposition-tests#encoding-2231-char> for details. At this time, the current versions of all major desktop user agents support it.
Note that the implementation in Internet Explorer 9 does not support the ISO-8859-1 character encoding; this document revision acknowledges that UTF-8 is sufficient for expressing all code points and removes the requirement to support ISO-8859-1.

The "Link" header field, on the other hand, was more recently specified in [RFC5988]. At the time of this writing, no user agent except Firefox supported the "title*" parameter (starting with release 15).

Section 3.4 of [RFC7616] defines the "username*" parameter for use in HTTP Digest Authentication. At the time of writing, no user agent implemented this extension.

Acknowledgements

Thanks to Martin Dürst and Frank Ellermann for help figuring out ABNF details, to Graham Klyne and Alexey Melnikov for general review, to Chris Newman for pointing out an RFC 2231 incompatibility, and to Benjamin Carlyle, Roar Lauritzsen, Eric Lawrence, and James Manger for implementers feedback.

Furthermore, thanks to the members of the IETF HTTP Working Group for the feedback specific to this update of RFC 5987.
