## Algorithm Implementation Requirements and Usage Guidance for DNSSEC

### Abstract

The DNSSEC protocol makes use of various cryptographic algorithms in order to provide authentication of DNS data and proof of nonexistence. To ensure interoperability between DNS resolvers and DNS authoritative servers, it is necessary to specify a set of algorithm implementation requirements and usage guidelines to ensure that there is at least one algorithm that all implementations support. This document defines the current algorithm implementation requirements and usage guidance for DNSSEC. This document obsoletes RFC 6944.

### Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 7841.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at <https://www.rfc-editor.org/info/rfc8624>.

## 1. Introduction

The DNSSEC signing algorithms are defined by various RFCs, including [RFC4034], [RFC5155], [RFC5702], [RFC5933], [RFC6605], and [RFC8080]. DNSSEC is used to provide authentication of data. To ensure interoperability, a set of "mandatory-to-implement" DNSKEY algorithms are defined. This document obsoletes [RFC6944].

### 1.1. Updating Algorithm Implementation Requirements and Usage Guidance

The field of cryptography evolves continuously. New, stronger algorithms appear, and existing algorithms are found to be less secure than originally thought. Attacks previously thought to be computationally infeasible become more accessible as the available computational resources increase. Therefore, algorithm implementation requirements and usage guidance need to be updated from time to time to reflect the new reality. The choices for algorithms must be conservative to minimize the risk of algorithm compromise.

### 1.2. Updating Algorithm Requirement Levels

The mandatory-to-implement algorithm of tomorrow should already be available in most implementations of DNSSEC by the time it is made mandatory. This document attempts to identify and introduce those algorithms for future mandatory-to-implement status. There is no guarantee that algorithms in use today will become mandatory in the future. Published algorithms are continuously subjected to cryptographic attack and may become too weak or even be completely broken before this document is updated.

This document only provides recommendations with respect to mandatory-to-implement algorithms or algorithms so weak that they cannot be recommended. Any algorithm listed in the [DNSKEY-IANA] and [DS-IANA] registries that are not mentioned in this document MAY be implemented. For clarification and consistency, an algorithm will be specified as MAY in this document only when it has been downgraded from a MUST or a RECOMMENDED to a MAY.

Although this document's primary purpose is to update algorithm recommendations to keep DNSSEC authentication secure over time, it also aims to do so in such a way that DNSSEC implementations remain interoperable. DNSSEC interoperability is addressed by an incremental introduction or deprecation of algorithms.

[RFC2119] considers the term SHOULD equivalent to RECOMMENDED, and SHOULD NOT equivalent to NOT RECOMMENDED. The authors of this document have chosen to use the terms RECOMMENDED and NOT

RECOMMENDED, as this more clearly expresses the intent to implementers.

It is expected that deprecation of an algorithm will be performed gradually in a series of updates to this document. This provides time for various implementations to update their implemented algorithms while remaining interoperable. Unless there are strong security reasons, an algorithm is expected to be downgraded from MUST to NOT RECOMMENDED or MAY, instead of to MUST NOT. Similarly, an algorithm that has not been mentioned as mandatory-to-implement is expected to be introduced with a RECOMMENDED instead of a MUST.

Since the effect of using an unknown DNSKEY algorithm is that the zone is treated as insecure, it is recommended that algorithms downgraded to NOT RECOMMENDED or lower not be used by authoritative nameservers and DNSSEC signers to create new DNSKEYs. This will allow for deprecated algorithms to become less and less common over time. Once an algorithm has reached a sufficiently low level of deployment, it can be marked as MUST NOT so that recursive resolvers can remove support for validating it.

Recursive nameservers are encouraged to retain support for all algorithms not marked as MUST NOT.

### 1.3. Document Audience

The recommendations of this document mostly target DNSSEC implementers, as implementations need to meet both high security expectations as well as high interoperability between various vendors and with different versions. Interoperability requires a smooth transition to more secure algorithms. This perspective may differ from that of a user who wishes to deploy and configure DNSSEC with only the safest algorithm. On the other hand, the comments and recommendations in this document are also expected to be useful for such users.

## 2. Conventions Used in This Document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

### 3. Algorithm Selection

#### 3.1. DNSKEY Algorithms

The following table lists the implementation recommendations for DNSKEY algorithms [DNSKEY-IANA].

Number	Mnemonics	DNSSEC Signing	DNSSEC Validation
1	RSAMD5	MUST NOT	MUST NOT
3	DSA	MUST NOT	MUST NOT
5	RSASHA1	NOT RECOMMENDED	MUST
6	DSA-NSEC3-SHA1	MUST NOT	MUST NOT
7	RSASHA1-NSEC3-SHA1	NOT RECOMMENDED	MUST
8	RSASHA256	MUST	MUST
10	RSASHA512	NOT RECOMMENDED	MUST
12	ECC-GOST	MUST NOT	MAY
13	ECDSAP256SHA256	MUST	MUST
14	ECDSAP384SHA384	MAY	RECOMMENDED
15	ED25519	RECOMMENDED	RECOMMENDED
16	ED448	MAY	RECOMMENDED

RSAMD5 is not widely deployed, and there is an industry-wide trend to deprecate MD5 usage.

RSASHA1 and RSASHA1-NSEC3-SHA1 are widely deployed, although the zones deploying it are recommended to switch to ECDSAP256SHA256 as there is an industry-wide trend to move to elliptic curve cryptography. RSASHA1 does not support NSEC3. RSASHA1-NSEC3-SHA1 can be used with or without NSEC3.

DSA and DSA-NSEC3-SHA1 are not widely deployed and are vulnerable to private key compromise when generating signatures using a weak or compromised random number generator.

RSASHA256 is widely used and considered strong. It has been the default algorithm for a number of years and is now slowly being replaced with ECDSAP256SHA256 due to its shorter key and signature size, resulting in smaller DNS packets.

RSASHA512 is NOT RECOMMENDED for DNSSEC signing because it has not seen wide deployment, but there are some deployments; hence, DNSSEC validation MUST implement RSASHA512 to ensure interoperability. There is no significant difference in cryptographic strength between RSASHA512 and RSASHA256; therefore, use of RSASHA512 is discouraged

as it will only make deprecation of older algorithms harder. People who wish to use a cryptographically stronger algorithm should switch to elliptic curve cryptography algorithms.

ECC-GOST (GOST R 34.10-2001) has been superseded by GOST R 34.10-2012 in [RFC7091]. GOST R 34.10-2012 hasn't been standardized for use in DNSSEC.

ECDSAP256SHA256 provides more cryptographic strength with a shorter signature length than either RSASHA256 or RSASHA512. ECDSAP256SHA256 has been widely deployed; therefore, it is now at MUST level for both validation and signing. It is RECOMMENDED to use the deterministic digital signature generation procedure of the Elliptic Curve Digital Signature Algorithm (ECDSA), specified in [RFC6979], when implementing ECDSAP256SHA256 (and ECDSAP384SHA384).

ECDSAP384SHA384 shares the same properties as ECDSAP256SHA256 but offers a modest security advantage over ECDSAP256SHA256 (192 bits of strength versus 128 bits). For most DNSSEC applications, ECDSAP256SHA256 should be satisfactory and robust for the foreseeable future and is therefore recommended for signing. While it is unlikely for a DNSSEC use case requiring 192-bit security strength to arise, ECDSA384SHA384 is provided for such applications, and it MAY be used for signing in these cases.

ED25519 and ED448 use the Edwards-curve Digital Security Algorithm (EdDSA). There are three main advantages of EdDSA: it does not require the use of a unique random number for each signature, there are no padding or truncation issues as with ECDSA, and it is more resilient to side-channel attacks. Furthermore, EdDSA cryptography is less prone to implementation errors ([RFC8032], [RFC8080]). It is expected that ED25519 will become the future RECOMMENDED default algorithm once there's enough support for this algorithm in the deployed DNSSEC validators.

### 3.2. DNSKEY Algorithm Recommendation

Due to the industry-wide trend towards elliptic curve cryptography, ECDSAP256SHA256 is the RECOMMENDED DNSKEY algorithm for use by new DNSSEC deployments, and users of RSA-based algorithms SHOULD upgrade to ECDSAP256SHA256.

### 3.3. DS and CDS Algorithms

The following table lists the recommendations for Delegation Signer Digest Algorithms [DS-IANA]. These recommendations also apply to the Child Delegation Signer (CDS) RRTYPE as specified in [RFC7344].

Number	Mnemonics	DNSSEC Delegation	DNSSEC Validation
0	NULL (CDS only)	MUST NOT [*]	MUST NOT [*]
1	SHA-1	MUST NOT	MUST
2	SHA-256	MUST	MUST
3	GOST R 34.11-94	MUST NOT	MAY
4	SHA-384	MAY	RECOMMENDED

[\*] - This is a special type of CDS record signaling removal of DS at the parent in [RFC8078].

NULL is a special case; see [RFC8078].

SHA-1 is still widely used for Delegation Signer (DS) records, so validators MUST implement validation, but it MUST NOT be used to generate new DS and CDS records (see "Operational Considerations" for caveats when upgrading from the SHA-1 to SHA-256 DS algorithm.)

SHA-256 is widely used and considered strong.

GOST R 34.11-94 has been superseded by GOST R 34.11-2012 in [RFC6986]. GOST R 34.11-2012 has not been standardized for use in DNSSEC.

SHA-384 shares the same properties as SHA-256 but offers a modest security advantage over SHA-256 (384 bits of strength versus 256 bits). For most applications of DNSSEC, SHA-256 should be satisfactory and robust for the foreseeable future and is therefore recommended for DS and CDS records. While it is unlikely for a DNSSEC use case requiring 384-bit security strength to arise, SHA-384 is provided for such applications, and it MAY be used for generating DS and CDS records in these cases.

### 3.4. DS and CDS Algorithm Recommendation

An operational recommendation for new and existing deployments:  
SHA-256 is the RECOMMENDED DS and CDS algorithm.

#### 4. Security Considerations

The security of cryptographic systems depends on both the strength of the cryptographic algorithms chosen and the strength of the keys used with those algorithms. The security also depends on the engineering of the protocol used by the system to ensure that there are no non-cryptographic ways to bypass the security of the overall system.

This document concerns itself with the selection of cryptographic algorithms for use in DNSSEC, specifically with the selection of "mandatory-to-implement" algorithms. The algorithms identified in this document as MUST or RECOMMENDED to implement are not known to be broken (in the cryptographic sense) at the current time, and cryptographic research so far leads us to believe that they are likely to remain secure into the foreseeable future. However, this isn't necessarily forever, and it is expected that new revisions of this document will be issued from time to time to reflect the current best practices in this area.

Retiring an algorithm too soon would result in a zone (signed with a retired algorithm) being downgraded to the equivalent of an unsigned zone. Therefore, algorithm deprecation must be done very slowly and only after careful consideration and measurement of its use.

#### 5. Operational Considerations

DNSKEY algorithm rollover in a live zone is a complex process. See [RFC6781] and [RFC7583] for guidelines on how to perform algorithm rollovers.

DS algorithm rollover in a live zone is also a complex process. Upgrading an algorithm at the same time as rolling a new Key Signing Key (KSK) will lead to DNSSEC validation failures. Administrators MUST complete the process of the DS algorithm upgrade before starting a rollover process for a new KSK.

#### 6. IANA Considerations

This document has no IANA actions.
