SNA APPN Node MIB

Status of this Memo

This memo provides information for the Internet community. This memo does not specify an Internet standard of any kind. Distribution of this memo is unlimited.

Abstract

This RFC describes IBM's SNMP support for SNA Advanced Peer-to-Peer Networking (APPN) nodes.

1.0 Introduction

This module contains managed objects which describe the following:

- o The APPN node (either an APPN network node or an APPN end node)
- o The connections of the node to other SNA nodes
- o The APPN network topology (as reflected in the network topology database that is replicated in each APPN network node).

This module does not describe the SNA logical units (LUs) served by the APPN node nor does it describe the sessions between LUs. Managed objects for that information are under development.

ibmappnNodePortDlcTracIndex OBJECT-TYPE
    SYNTAX INTEGER
    ACCESS read-only
    STATUS mandatory
    DESCRIPTION
        "This index value is updated every time a new trace entry
         is created which provides a means to retrieve only the
         updated entries and also provides a simple method of
         correlating the entries. The table will wrap when the
         table is full, which will result in previous entries
         being written over. The management station can overcome
         this by retrieving the table using this index to"

```

```

retrieve only the new table entries.

-- Network nodes
-- The APPN topology database consists of information about every
-- APPN network node. This information is learned over time
-- as each network node exchanges topology information with
-- each of its adjacent network nodes. The database consists
-- of information about each node and all of the transmissions
-- groups used by each node.

-- Virtual nodes
-- Information about virtual nodes (connection networks) is treated
-- the same as information about network node
-- and is replicated at each network node.
-- The node name is the only meaningful information. The other
-- node objects use default values. Each node that has defined
-- a TG with this virtual node as the destination also defines a
-- TG on this virtual node. There is a TG record for each node
-- that uses this virtual node.
--
-- The APPN node table represents the APPN topology
-- database with the APPN CP fully-qualified name
-- being used as the index to this table.
-- This entire table could be retrieved using the GET NEXT command,
```

```
-- however, due to the dynamics of APPN, nodes could come and
-- go and status could change as the table is being
-- retrieved. Although in most cases the data retrieved will be valid,
-- missing and invalid status could cause problems for
-- a management application that was graphically displaying
-- this data.
-- This potential problem can be eliminated by
-- retrieving the FRSN before and after completion
-- of retrieval of the APPN topology table.
-- If the FRSN has changed, then repeat the
-- retrieval of the entire topology table
-- until the FRSN remains unchanged.
-- Object 'appnNnFrsn' represents the last
-- change or update to this node's topology
-- database.
--
--
-- The format of the actual database is as follows:
--
-- Node table (entry for each node in network)
-- TG table (entry for each TG owned by node)
--
-- Due to SNMP ASN.1 limitations, we cannot represent
-- the TG table within the node table. We define
-- separate tables for nodes and TGS, adding the node
-- name to each TG entry to provide a means of
-- correlating each TG with its originating node.
```

```

```
-- The APPN Class of Service (COS)
```

```
-- Class of Service is a means of expressing the quality of the routes
-- and the transmission priority of traffic which flows on these routes.
-- The quality of routes is specified by two tables, a COS weight table
-- for TGs and a COS weight table for nodes. These COS tables are
-- administratively assigned at each APPN node. Seven default tables
-- for TGs and a COS weight table for Nodes. These COS tables are
-- administratively assigned at each APPN node with seven default tables
-- being provided by IBM.
```

```
--
```

```
--
```

```
-- COS Name
--     Unqualified name identifying the class of service.
-- Transmission priority
```

```
--      Transmission priority associated with this class of service
-- COS Node Row Table
--      At least one node row must be specified. The default
--      COS tables specify 8 rows.
-- Node Row Weight
--      Numeric value between 0 and 255 inclusive indicating
--      the weight associated with this row.
-- Route addition resist (min)
--      Numeric value between 0 and 255 inclusive indicating
--      the minimum route addition resistance for this row.
-- Route addition resist (max)
--      Numeric value between 0 and 255 inclusive indicating
--      the maximum route addition resistance for this row.
-- Congestion      (min)
--      Indicates whether this class of service for this row
--      will accept congestion. Yes or No must be specified.
-- Congestion      (max)
--      Indicates whether this Class of Service for this row
--      will accept congestion. Yes or No must be specified.
--
-- COS TG Row table
--      At least one TG row must be specified with the defaults
--      COS tables specify 8 rows.
