DNS Centrality

Geoff Huston AM
APNIC
This Presentation

• What’s the problem with centrality anyway?
• What does centrality in the DNS mean?
• How to measure DNS centrality
• What we measured
• What I think it means

All in 20 minutes!
Why pick on the DNS?

The DNS is **used by everyone and everything**

- Because pretty much everything you do on the net starts with a call to the DNS
- If a single entity “controlled” the entire DNS then to all practical purposes that entity would control not just the DNS, but the entire Internet!
Centrality is today's Internet

• Many aspects of the Internet’s infrastructure are operated by fewer and fewer entities over time
  • Shift from entrepreneurial ventures to established business practices have largely driven these broad changes that have resulted in amalgamation and market concentration in many aspects of the Internet’s service provision
• Competition has been replaced by Oligarchies
What's the problem?

- Economics A01 (or Adam Smith’s Invisible Hand)
  - Competition rewards efficient producers
  - Innovation that increases production efficiency is rewarded
  - Consumers benefit from increased production efficiency and innovation
- Consolidation in the market
  - Distorts the functions of an open competitive market
  - Decreases competition pressure
  - Creates barriers to entry in the market
  - Reduces pressure for increased production efficiency and innovation
  - Consumers end up paying a premium
Consolidation in the DNS

It’s not a new topic:

• For many years BIND was a defacto monopoly provider for DNS software. At the time almost every DNS recursive resolver and authoritative server ran BIND software
• Due to a deliberate effort to broaden the DNS resolver space from a monoculture to a richer space, this picture has broadened out to a number of DNS software platforms and is less of a concern these days

• But there are many other places where the DNS is aggregating
  • Name Registration services
  • Name Hosting service providers
  • Name Resolution providers
Let's Focus!

• Here we are going to concentrate on just one of these areas
• We will look at the recursive resolver market and try to understand the extent to which we are seeing consolidation of the recursive name resolution function
• And then assess to what extent this represents a source of concern in the DNS
Recursive Resolvers

• This function is generally bundled with an ISP’s access service for public network services

• Which means that there is already some level of consolidation in this space as the concentration of these DNS services follows the concentration of ISPs in the retail market

Aside: Concentration in the retail ISP market

The ISP retail access market is already heavily concentrated/centralised:

• 10 ISPs serve some 30% of the Internet’s user base
• 90% of users are served by 1,000 ISPs
DNS Recursive Resolvers

• This function is generally bundled with an ISP’s access service for public network services
  • So we would expect to see a level of concentration in recursive resolvers in line with the concentration in the ISP access market

• The question is: Is there consolidation in the DNS recursive resolution function over and above the existing access market consolidation?

• Where might we see such consolidation?
Open DNS Resolvers

• There are some 6M open DNS resolvers in operation today*
• Most of these appear to be inadvertently open due to errant CPE equipment
  • Where the resolver implementation does not correctly distinguish between “inside” and “outside” and provides a resolution service on all interfaces
• That may sound like a large number, but it has got a whole lot better over time!
  • 33M open resolvers were seen in 2013 **

* https://scan.shadowserver.org/dns/
** https://indico.dns-oarc.net/event/0/contributions/1/attachments/19/125/201305-dnsoarc-mauch-openresolver.pdf
Open DNS Resolvers as a Service

• Others are explicitly configured to offer DNS resolution services as a open service
  • Hard to say where all this started, but an early example was the the 4.2.2.2 open resolver project offered by BBN Planet in the mid-90’s, though there were many others even then
    • At that time many ISPs used recursive resolvers as a service and some operated these platforms as a open service as a least cost / lowest admin overhead option
  • The use of anycast in the DNS made it possible to operate a single service with a distributed footprint
  • OpenDNS was one of the early offerings of a dedicated recursive resolution service with a scaled up infrastructure
  • Google Public DNS entered the picture with a service that took scaling to the next level

* https://scan.shadowserver.org/dns/
What’s the Centrality Question here?

• One way to measure centrality is by “market share”
• So the market share question here would be: What proportion of users of the Internet use <X> as their DNS resolver?
  • We won’t distinguish between end users explicitly adding their own DNS configuration into their platform and ISPs using forwarding structures to pass all DNS queries to an open resolver. Through the lens of “centrality” both paths to using open DNS resolvers look the same!
How we* Measure DNS Centrality

• We use Google Ads as the main element of this measurement
  • The measurement script is an embedded block of HTML5 code in an Ad
  • The Ad runs in campaigns that generate some 10M impressions per day
  • We get to “see” the DNS in operation from the inside of most mid-to-large ISPs and service providers across the entire Internet

• Ads provide very little functionality in the embedded scripts – it’s basically limited to fetching URLs
  • But that’s enough here, as a URL fetch involves the resolution of a domain name
  • So we use unique DNS names in every ad, so the DNS queries will be passed through to our authoritative servers

* by “we” I mean APNIC Labs!
How we Measure DNS Centrality

Ad delivery

Stub-to-recursive DNS Query

User-to-recursive resolver mapping

Resolver Engine

Recursive-to-Authoritative DNS Query

Authoritative Server
Recursive Resolver Behaviours

- The task is to match the source of a query of a domain name to both a resolver and an end user

- We need to
  - map query IP source addresses to resolvers
  - understand how the DNS “manages” queries
  - how the resolver lists in /etc/resolv.conf are used
Mapping Resolver Addresses

- We use periodic sweeps with RIPE Atlas to reveal the engine addresses used by popular Open DNS resolvers, and load this into an identification database
Understanding Resolver Behaviour

From Client

Service Address

Query Distributor

Resolver Engine

Resolver Engine

Resolver Engine

Resolver Engine

Engine Address

To Server
Resolution Metrics

• Average query count per unique name: 3.4
  (Dual stack hosts may be a factor here)
  • Max observed query count in 30 seconds is 1,761 queries!
Resolution Metrics

- Average number of resolvers (IP addresses) per unique name: 2.1
- 30 second maximum resolvers seen: 94
First Resolver vs Full Resolver Set

• What happens if the authoritative server always reports SERVFAIL to all queries?
• We use a server that always returns a SERVFAIL error code to prompt the client to run through its full set of recursive resolvers
SERVFAIL Resolution Metrics

- Average query count per unique name: 36.5
- Max observed query count in 30 seconds is 292,942 queries!  (yes, really!)
SERVFAIL Resolution Metrics

- Average number of resolvers (IP addresses) per unique name: 8.9
- 30 second maximum resolvers seen: 1,368
Of the 140,000 visible recursive resolvers, just 150 resolvers account for 20% of all users and 1,500 resolvers account for 50% of all users.

10,000 resolvers account for 90% of all users

However we are looking here at resolver IP addresses, and that’s probably misleading.

Let's try and group resolver IP addresses into resolver services*

* Use techniques of common origin AS, direct probing with RIPE Atlas and (occasionally) operator provided lists
Of the 14,600 visible recursive resolvers services, just 15 resolver services serve 50% of users

250 resolver services serve 90% of users

Is this what we mean by “centralisation”? 
Details

Let's break this data down into:

- Using a “known” open DNS resolver
- Using a resolver in the same AS as the user
- Using a resolver in the same country as the user
- Others
"First" Resolver Use

65% of users use a resolver located in the same AS as the user (ISP resolver)

17% of users use a resolver located in the same CC as the user (ISP resolver?)

17% of users use the Google open resolver (8.8.8.8)
All Resolver Use (SERVFAIL)

Experiment Failure

65% -> 69% for same ISP

15% -> 29% for Google use

(yes, the plotting software performed a colour change - sorry!)
Google DNS

Use of Google Service per CC

Within each country how many users (%) in that country use Google’s resolver service?
Looking at the total population of users using Google’s service, where are they located?
Google DNS

- Google DNS use appears to be equally split between first use (15% of users) and backup resolvers (a further 14% of users)
- Within each economy Google DNS is heavily used in some African economies, and central and southern Asian economies
- The largest pool of Google DNS users are located in India (19% of Google DNS users)
- Significant pools Google users are also seen in the US, China, Nigeria, Brazil and Iran (each CC has some 4% - 6% of Google’s DNS users)
Cloudflare's 1.1.1.1 service

Where is Cloudflare used?

Cloudflare is extensively used in Turkmenistan (80%), Iran (57%), Niger (54%), Cameroon (54%) and the Congo (49%).

Cloudflare User breakdown?
Quad9 service

Quad9 market share

Where is Quad9 used?

Quad9 User breakdown?
A major ISP in IRAN, MCCI, distributes its queries across Google, Cloudflare, Yandex, Neustar, OpenDNS, Quad9 and others – all at once!
Who makes the choice?

• Is this the ISP’s resolver performing forwarding of the query to an open resolver, or the users themselves opting out of the ISP service?
  • The numbers vary, but it is quite common to see 60% - 80% of users in an AS having their queries sent to an open resolver when open resolvers are used
Who makes the choice?

• Is this the ISP’s resolver performing forwarding of the query to an open resolver, or the users themselves opting out of the ISP service?
  • The numbers vary, but it is quite common to see 60% - 80% of users in an AS having their queries sent to an open resolver when open resolvers are used.

Resolver Use – AS131429, Mobifone, Vietnam

- Google DNS at 90%
- OpenDNS at 20%
DNS Use in Hong Kong

[Graph showing DNS resolver usage in Hong Kong with indicators for ISP Resolver, Google, Other HK, Other Country, Cloudflare]
Resolver Centrality?

• It’s not a “small number” of open resolvers
  • It’s actually just 1 – Google’s Public DNS

• It’s not end users reconfiguring their devices
  • It’s the ISP
  • And where it’s not the ISP it’s mainly enterprise customers of ISPs

• Is this changing?
  • Yes, but quite slowly
Commentary and Opinions

What follows are my opinions!
Is this a centrality "problem"?

• Is this an emerging distortion of the market that puts excessive market control in the hands of a small set of providers?
  • A lot of users have the DNS queries passed on to authoritative servers via Google’s open resolver service
  • But does this present us with issues?
    • 8.8.8.8 is fast, supports DNSSEC validation and does not filter or alter DNS responses (as far as I am aware)
    • It’s cheap, its fast, its well managed, and it works reliably
    • So what’s the issue here?
THE RUMORS ARE TRUE. GOOGLE WILL BE SHUTTING DOWN PLUS—ALONG WITH HANGOUTS, PHOTOS, VOICE, DOCS, DRIVE, MAPS, GMAIL, CHROME, ANDROID, AND SEARCH—TO FOCUS ON OUR CORE PROJECT: THE 8.8.8.8 DNS SERVER.

https://xkcd.com/1361/
What's the problem here?

- It’s a sensitive issue these days
- There are many privacy undertakings in our space, but the undeniable fact is that many “free” services are indirectly funded through advertising revenue, and advertising is based on individual tracking and profiling
- Open DNS providers typically provide undertakings that they do not use their query traffic for profiling - and I have no evidence that these undertakings are not being adhered to

  But I still have some questions as a consumer of their services:
  - How are these undertakings audited and/or enforced? By whom?
  - Are there penalties for breaches of these undertakings?
  - Considering the size of these actors are any of these penalties even meaningful?
Barriers to Entry

• Why is there only 1 very large open DNS provider in today’s Internet?
• Is it because the incumbent is raising the barriers of entry to all potential competitors?
  • Unlikely, as there is no evidence that this is the case
• Or are there “natural” barriers to entry?
  • Possibly – let’s look
"Natural" Barriers to DNS Entry

- The DNS economy is such a financial wasteland that very few have a natural incentive to enter this market
  - No one pays for queries!
    - Selling query logs can very damaging in terms of reputation and liability – particularly when you cannot get the users’ informed consent to do so
    - Selling NXDOMAIN substitution is also very damaging in terms of reputation
  - It can be argued* that only someone with a massive presence is search has a commercial case for deploying a DNS resolver that is “honest” about the DNS (including NXDOMAIN)

* And some have from time to time
But...
Is all this a distraction?

• It’s more likely that the shift of DNS functions into application realms using DoH services as an application function is a far greater threat to the current model of the DNS as a common single infrastructure

• Maybe the convergence of:
  • increased autonomy of applications in today’s Internet
  • the dominant position of Android
  • the dominant position of Chrome

poses a greater potential threat to the integrity of the name infrastructure of the Internet than the issue of recursive resolver use
Is this a problem?

• If applications develop their own application-centric name universes then what is the issue here?

• While we’ve used a single name space for the past 40 years or so, that does not mean that we have to keep on doing so

• And just because many others use a single name space as a means of surveillance and imposed control does not mean that we have to keep on using this single name space
  • Particularly when applications can be far more effective in cloaking the user’s interactions in the application space than we’ve been able to do in a single DNS so far
Maybe this is a Good Thing

• Again, it could be argued that this deliberate fragmentation of a single cohesive name space for the Internet into a set of application-specific spaces is a shift that lies in protecting the interests of privacy and service integrity for users

• Its early days, and right now we just don’t know!
Watch This Space

The Internet remains one where the stasis of incumbent services has to compete against the pressure of continued innovation.

While the pressures of aggregation and centralisation are evident in the space of common infrastructure services such as bandwidth, the DNS and CDN services, innovation in the Internet is moving up into the application space.

We are inexorably moving to application-centric networking where both the network and the platforms are stripped back and the functionality and value is loaded into application-environments.
Thanks!
